### The first part of this lecture is based primarily on the paper:

M. Yu and A. Nagurney, "Competitive Food Supply Chain Networks with Application to Fresh Produce," *European Journal of Operational Research* **224(2)** (2013), pp 273-282

where a full list of references can be found, along with some additional results.

## Outline

- Background and Motivation
- Literature Review
- The Fresh Produce Supply Chain Network Oligopoly Model
- Case Study
- Relationship of the Model to Others in the Literature
- Quality Decay of Fresh Produce and Farmers' Markets
- Summary

## Motivation

The fundamental difference between **food supply chains** and other supply chains is the **continuous and significant change in the quality** of food products throughout the entire supply chain until the points of final consumption.

# Globalization of Food Supply Chains

Consumers' **expectation of year-around availability** of fresh food products has encouraged the globalization of food markets.

- The consumption of **fresh vegetables** has increased at a much faster pace than the demand for traditional crops such as wheat and other grains (USDA (2011)).
- In the US alone, consumers now spend over 1.6 trillion dollars annually on food (Plunkett Research (2011)).
- The United States is ranked **number one as both importer and exporter** in the international trade of horticultural commodities (Cook (2002)).

The growing **global competition**, coupled with the associated **greater distances** between food production and consumption locations, creates new challenges for food supply chain management.

# Food Waste/Loss

- It is estimated that approximately **one third** of the global food production is wasted or lost annually (Gustavsson et al. (2011)).
- In any country, 20%-60% of the total amount of agricultural fresh products has been wasted or lost (Widodo et al. (2006)).
  - In **developed countries**, the overall average losses of fruits and vegetables during **post-production supply chain activities** are approximately 12% of the initial production.
  - The corresponding losses in **developing regions** are even **severer**.

Professor Anna Nagurney

Masterclass - Network Equilibrium

Given the thin profit margins in the food industries, **product differentiation strategies** are increasingly used in food markets (Lowe and Preckel (2004), Lusk and Hudson (2004), and Ahumada and Villalobos (2009)) with **product freshness** considered one of the differentiating factors (Kärkkäinen (2003) and Lütke Entrup et al. (2005)).

- One successful example is fresh-cut produce, including bagged salads, washed baby carrots, and fresh-cut melons (Cook (2002)).
- Retailers, such as Globus, a German retailer, are also now realizing that **food freshness can be a competitive advantage** (Lütke Entrup et al. (2005)).

# The Fresh Produce Supply Chain Network Oligopoly Model

This model focuses on **fresh** produce items, such as vegetables and fruits.

- They require simple or limited processing.
- The life cycle can be measured in days.

# The Fresh Produce Supply Chain Network Topology

- The / food firms compete
   noncooperatively in an oligopolistic
   manner.
- The products may be differentiated, due to product freshness and food safety concerns.

## Food Production

## Food Processing

## Food Storage

## Food Shipment/Distribution

- Most of fresh produce items reach their peak quality at the time of production, and then **deteriorate substantially over time**.
- The decay rate varies significantly
  - With different temperatures, and
  - Under other environmental conditions.

The food products **deteriorate over time** even **under optimal conditions**.

- Most of fresh produce items reach their peak quality at the time of production, and then **deteriorate substantially over time**.
- The decay rate varies significantly
  - With different temperatures, and
  - Under other environmental conditions.

The food products **deteriorate over time** even **under optimal conditions**.

**Microbiological decay** is one of the major causes of the food quality degradation, especially for the fresh produce.

Therefore, food deterioration usually follows the first-order reactions with **exponential time decay**.

- The decrease in quantity represents the number of units of decayed products (e.g. vegetables and fruits).
- The degradation in quality emphasizes that all the products deteriorate at the same rate simultaneously (e.g. meat, dairy, and bakery products).

The model adopts exponential time decay so as to capture the discarding of spoiled products associated with **the post-production** supply chain activities.

Each unit has a probability of  $e^{-\lambda t}$  to survive another t units of time, where  $\lambda$  is the decay rate, which is given and fixed. Let  $N_0$  denote the quantity at the beginning of the time interval (link). Hence, the expected quantity surviving at the end of the time interval (specific link), denoted by N(t), can be expressed as:

$$N(t) = N_0 e^{-\lambda t}.$$
 (1)

## How to Handle Food Deterioration

Let  $\alpha_a$  denote **the throughput factor** associate with every link *a* in the supply chain network, which lies in the range of (0, 1].

• For a production link:

$$\alpha_a = 1, \tag{2a}$$

• For a post-production link:

$$\alpha_a = e^{-\lambda_a t_a}, \tag{2b}$$

where  $\lambda_a$  and  $t_a$  are the decay rate and the time duration associated with the link *a*, respectively, which are given and fixed.

In rare cases, food deterioration follows the zero order reactions with linear decay. Then,  $\alpha_a = 1 - \lambda_a t_a$  for a post-production link.

### **Total Discarding Cost Functions**

$$\hat{z}_a = \hat{z}_a(f_a), \quad \forall a \in L,$$
 (5)

which is assumed to be convex and continuously differentiable.

- It is imperative to **remove the spoiled fresh food products** from the supply chain network.
  - For instance, fungi are the common post-production diseases of fresh fruits and vegetables, which can colonize the fruits and vegetables rapidly.
- The model mainly focuses on the disposal of the decayed food products at the processing, storage, and distribution stages.

## How to Handle Food Deterioration

### Multiplier $\alpha_{ap}$

$$\alpha_{ap} \equiv \begin{cases} \delta_{ap} \prod_{b \in \{a' < a\}_p} \alpha_b, & \text{if } \{a' < a\}_p \neq \emptyset, \\ \\ \delta_{ap}, & \text{if } \{a' < a\}_p = \emptyset, \end{cases}$$
(6)

where  $\{a' < a\}_p$  denotes the set of the links preceding link *a* in path *p*, and  $\emptyset$  denotes the null set.

### Relationship between Link Flows, $f_a$ , and Path Flows, $x_p$

$$f_{a} = \sum_{i=1}^{I} \sum_{k=1}^{n_{R}} \sum_{p \in P_{k}^{i}} x_{p} \alpha_{ap}, \quad \forall a \in L.$$

$$(7)$$

Path Multiplier  $\mu_p$ 

$$\mu_{p} \equiv \prod_{a \in p} \alpha_{a}, \quad \forall p \in P_{k}^{i}; \ i = 1, \dots, I; \ k = 1, \dots, n_{R}.$$
(8)

Relationship between Path Flows,  $x_p$ , and demands,  $d_{ik}$ 

$$\sum_{p \in P_k^i} x_p \mu_p = d_{ik}, \quad i = 1, \dots, I; \ k = 1, \dots, n_R.$$
(9)

 $d_{ik}$  can capture **production differentiation**, due to food safety and health concerns.

### **Demand Price Functions**

$$\rho_{ik} = \rho_{ik}(d), \quad i = 1, \dots, I; \, k = 1, \dots, n_R,$$
(10)

which captures the demand-side competition. These demand price functions are assumed to be continuous, continuously differentiable, and monotone decreasing.

#### Total Operational Cost Functions

$$\hat{c}_a = \hat{c}_a(f), \quad \forall a \in L,$$
 (11)

where f is the vector of all the link flows. Such cost functions can capture the supply-side competition. The total cost on each link is assumed to be convex and continuously differentiable.

### The Profit Function of Firm i

$$U_{i} = \sum_{k=1}^{n_{R}} \rho_{ik}(d) d_{ik} - \sum_{a \in L^{i}} \left( \hat{c}_{a}(f) + \hat{z}_{a}(f_{a}) \right).$$
(12)

In this oligopoly competition problem, the strategic variables are the path flows.

- X<sub>i</sub>: the vector of path flows associated with firm *i*; *i* = 1,...,*I*.
- X: the vector of all the firm' strategies, that is,  $X \equiv \{\{X_i\} | i = 1, ..., I\}.$

### Definition: Supply Chain Network Cournot-Nash Equilibrium

A path flow pattern  $X^* \in K = \prod_{i=1}^{l} K_i$  is said to constitute a supply chain network Cournot-Nash equilibrium if for each firm *i*; i = 1, ..., l:

$$U_i(X_i^*, \hat{X}_i^*) \ge U_i(X_i, \hat{X}_i^*), \quad \forall X_i \in K_i,$$
 (13)

where 
$$\hat{X}_{i}^{*} \equiv (X_{1}^{*}, \dots, X_{i-1}^{*}, X_{i+1}^{*}, \dots, X_{l}^{*})$$
 and  $K_{i} \equiv \{X_{i} | X_{i} \in R_{+}^{n_{Pi}}\}.$ 

### An equilibrium is established if NO firm can unilaterally improve its profit, given other firms' decisions.

### Variational Inequality Formulation

We first define:  $K^1 \equiv \{x | x \in R_+^{n_P}\}$ , and for each path  $p; p \in P_k^i$ ;  $i = 1, ..., I; k = 1, ..., n_R$ ,

$$\frac{\partial \hat{\mathcal{C}}_{p}(x)}{\partial x_{p}} \equiv \sum_{a \in L^{i}} \sum_{b \in L^{i}} \frac{\partial \hat{c}_{b}(f)}{\partial f_{a}} \alpha_{ap}$$

$$\frac{\partial \hat{Z}_{p}(x)}{\partial x_{p}} \equiv \sum_{a \in L^{i}} \frac{\partial \hat{z}_{a}(f_{a})}{\partial f_{a}} \alpha_{ap},$$

and

$$\frac{\partial \hat{\rho}_{il}(x)}{\partial x_p} \equiv \frac{\partial \rho_{il}(d)}{\partial d_{ik}} \mu_p.$$

### Variational Inequality (Path Flows)

Determine  $x^* \in K^1$  such that:

$$\sum_{i=1}^{I} \sum_{k=1}^{n_{R}} \sum_{p \in P_{k}^{i}} \left[ \frac{\partial \hat{C}_{p}(x^{*})}{\partial x_{p}} + \frac{\partial \hat{Z}_{p}(x^{*})}{\partial x_{p}} - \hat{\rho}_{ik}(x^{*})\mu_{p} - \sum_{l=1}^{n_{R}} \frac{\partial \hat{\rho}_{il}(x^{*})}{\partial x_{p}} \sum_{p \in P_{l}^{i}} \mu_{p} x_{p}^{*} \right] \times [x_{p} - x_{p}^{*}] \ge 0, \quad \forall x \in K^{1}.$$
(14)

Proof: See Masoumi, Yu, and Nagurney (2012).

Variational Inequality (Link Flows)

wh

Determine  $(f^*, d^*) \in K^2$ , such that:

$$\sum_{i=1}^{l} \sum_{a \in L^{i}} \left[ \sum_{b \in L^{i}} \frac{\partial \hat{c}_{b}(f^{*})}{\partial f_{a}} + \frac{\partial \hat{z}_{a}(f^{*}_{a})}{\partial f_{a}} \right] \times [f_{a} - f^{*}_{a}]$$
$$+ \sum_{i=1}^{l} \sum_{k=1}^{n_{R}} \left[ -\rho_{ik}(d^{*}) - \sum_{l=1}^{n_{R}} \frac{\partial \rho_{il}(d^{*})}{\partial d_{ik}} d^{*}_{il} \right] \times [d_{ik} - d^{*}_{ik}] \ge 0,$$
$$\forall (f, d) \in K^{2}, \qquad (15)$$
where  $K^{2} = \{(f, d) | x \ge 0, and(7), and(9), bold\}$ 

# Standard Form

Variational inequalities (14) and (15) can be put into standard form (see Nagurney (1999)): determine  $X^* \in \mathcal{K}$  such that:

$$\langle {\mathcal F}(X^*), X-X^*
angle \geq 0, \quad orall X \in {\mathcal K},$$

where  $\langle\cdot,\cdot\rangle$  denotes the inner product in *n*-dimensional Euclidean space. Let  $X\equiv x$  and

$$F(X) \equiv \left[\frac{\partial \hat{C}_{p}(x)}{\partial x_{p}} + \frac{\partial \hat{Z}_{p}(x)}{\partial x_{p}} - \hat{\rho}_{ik}(x)\mu_{p} - \sum_{l=1}^{n_{R}} \frac{\partial \hat{\rho}_{il}(x)}{\partial x_{p}} \sum_{q \in P_{l}^{i}} \mu_{q} x_{q};\right]$$
$$p \in P_{k}^{i}; i = 1, \dots, l; k = 1, \dots, n_{R},$$

and  $\mathcal{K} \equiv \mathcal{K}^1$ , then (14) can be re-expressed as above. Similarly, the variational inequality in terms of link flows can be put into standard form.

### Existence

Since the feasible sets of the above variational inequalities are not compact (closed and bounded) we don't have existence of solutions solely under the assumption of continuity of F(X). Instead, we have the following result.

### Existence Theorem

There exists at least one solution to variational inequality (14) (equivalently, to (15)), since there exists a b > 0, such that variational inequality

$$\langle F(X^b), X - X^b \rangle \ge 0, \quad \forall X \in \mathcal{K}_b,$$
 (16)

admits a solution in  $\mathcal{K}_b$  with

$$a^b \leq b.$$
 (17)

#### Uniqueness Theorem

Moreover, if the function F(X) of variational inequality (15) is strictly monotone on  $\mathcal{K} \equiv K^2$ , that is,

$$\langle (F(X^1) - F(X^2)), X^1 - X^2 \rangle > 0, \quad \forall X^1, X^2 \in \mathcal{K}, X^1 \neq X^2,$$
(18)

then the solution to variational inequality (15) is unique, that is, the equilibrium link flow pattern and the equilibrium demand pattern are unique.

## Algorithm – Euler Method

At an iteration  $\tau$  of the Euler method (see Dupuis and Nagurney (1993) and Nagurney and Zhang (1996)) one computes:

$$X^{\tau+1} = P_{\mathcal{K}}(X^{\tau} - a_{\tau}F(X^{\tau})), \qquad (19)$$

where  $P_{\mathcal{K}}$  is the projection on the feasible set  $\mathcal{K}$  and F is the function that enters the variational inequality problem.

### Closed Form Expression for Fresh Produce Path Flows

$$x_{p}^{\tau+1} = \max\{0, x_{p}^{\tau} + a_{\tau}(\hat{\rho}_{ik}(x^{\tau})\mu_{p} + \sum_{l=1}^{n_{R}} \frac{\partial \hat{\rho}_{il}(x^{\tau})}{\partial x_{p}} \sum_{q \in P_{l}^{i}} \mu_{q} x_{q}^{\tau} - \frac{\partial \hat{C}_{p}(x^{\tau})}{\partial x_{p}} - \frac{\partial \hat{Z}_{p}(x^{\tau})}{\partial x_{p}})\}, \quad \forall p \in P_{k}^{i}; i = 1, \dots, l; k = 1, \dots, n_{R}.$$
(20)

As shown in Dupuis and Nagurney (1993) and Nagurney and Zhang (1996), for convergence of the general iterative scheme, which induces the Euler method, the sequence  $\{a_{\tau}\}$  must satisfy:  $\sum_{\tau=0}^{\infty} a_{\tau} = \infty$ ,  $a_{\tau} > 0$ ,  $a_{\tau} \to 0$ , as  $\tau \to \infty$ .

Specific conditions for convergence of this scheme as well as various applications to the solutions of network oligopolies can be found in Nagurney and Zhang (1996), Nagurney, Dupuis, and Zhang (1994), Nagurney (2010), Nagurney and Yu (2012), and Masoumi, Yu, and Nagurney (2012).

Most of cantaloupes consumed in the United States are originally produced in California, Mexico, and in some countries in Central America.

- Typically, cantaloupes can be stored for 12–15 days at 2.2° to 5°C (36° to 41°F).
- It has been noticed that the decay of cantaloupes may result from such post-production disease, depending on the <u>season</u>, the <u>region</u>, and the <u>handling technologies</u> utilized between production and consumption.

 $M_2^2$  • Firm 1 is located in California.

- Firm 2 is located in Central America.
- All the distribution centers and the demand markets are located in the United States.
- Consumers at the demand markets were **indifferent** between cantaloupes of Firm 1 and Firm 2.
- Consumers at demand market  $R_2$  were willing to pay relatively more as compared to those at demand market  $R_1$ .

#### The Demand Price Functions

$$\rho_{11} = -.0001 d_{11} - .0001 d_{21} + 4, \quad \rho_{12} = -.0001 d_{12} - .0001 d_{22} + 6;$$

 $\rho_{21} = -.0001d_{21} - .0001d_{11} + 4, \quad \rho_{22} = -.0001d_{22} - .0001d_{12} + 6.$

- There is no shipment from distribution centers  $D_2^1$  and  $D_2^2$  to demand market  $R_1$ .
- The volume of product flows on distribution link 22 (or link 26) is higher than that of distribution link 20 (or link 24), which indicates that it is more cost-effective to provide fresh fruits from the nearby distribution centers.

$$d_{11}^* = 7.86, \quad d_{12}^* = 123.62, \quad d_{21}^* = 27.19, \text{ and } d_{22}^* = 139.38.$$

The Equilibrium Prices

$$\rho_{11} = 4.00, \quad \rho_{12} = 5.97, \quad \rho_{21} = 4.00, \quad \text{and} \quad \rho_{22} = 5.97.$$

#### The Profits of Two Firms

$$U_1 = 370.46$$
 and  $U_2 = 454.72$ .

 Since consumers do not differentiate the cantaloupes produced by these two firms, the prices of these two firms' cantaloupes at each demand market are identical.

・ 同・ ・ ヨ・

$$d_{11}^* = 7.86, \quad d_{12}^* = 123.62, \quad d_{21}^* = 27.19, \quad \text{and} \quad d_{22}^* = 139.38.$$

• The distribution links: 20, 21, 24, and 25, have zero product flows, since the extremely low demand price cannot cover the costs associated with long-distance distribution.

$$d_{11}^* = 4.51, \quad d_{12}^* = 3.24, \quad d_{21}^* = 5.96, \quad \text{and} \quad d_{22}^* = 4.21.$$

### The Equilibrium Prices

$$\rho_{11} = 0.49, \quad \rho_{12} = 0.49, \quad \rho_{21} = 0.49, \quad \text{and} \quad \rho_{22} = 0.49.$$

#### The Profits of Two Firms

$$U_1 = 1.16$$
 and  $U_2 = 1.63$ .

- The demand for cantaloupes is battered by the cantaloupe-associated outbreak, with significant decreases in demand prices at demand markets  $R_1$  and  $R_2$ .
- Both Firm 1 and Firm 2, in turn, experience dramatic declines in their profits.

### Case 3

- Firm 1 would like to regain consumers' confidence in its own product after the cantaloupe-associated outbreak.
- Firm 1 had its label of cantaloupes redesigned.
  - The label incorporates the guarantee of food safety.
  - The label also causes additional expenditures associated with its processing activities.

#### The Demand Price Functions

$$\rho_{11} = -.001d_{11} - .0005d_{21} + 2.5, \quad \rho_{12} = -.0003d_{12} - .0002d_{22} + 3;$$

$$\rho_{21} = -.001d_{21} - .001d_{11} + .5, \quad \rho_{22} = -.001d_{22} - .001d_{12} + .5.$$

24	.020	3.00	.942	$.015f_{24}^2 + .1f_{24}$	$.001f_{24}^2 + 0.02f_{24}$	0.00
25	.020	3.00	.942	$.015f_{25}^2 + .1f_{25}$	$.001f_{25}^2 + 0.02f_{25}$	0.00
26	.020	1.00	.980	$.005f_{26}^2 + .01f_{26}$	$.001f_{26}^2 + 0.02f_{26}$	3.65

<ロ> <同> <同> <同> < 同> < 同> < □> <

$$d_{11}^* = 17.52, \quad d_{12}^* = 46.46, \quad d_{21}^* = 5.81, \quad \text{and} \quad d_{22}^* = 3.58.$$

### The Equilibrium Prices

$$\rho_{11} = 2.48, \quad \rho_{12} = 2.99, \quad \rho_{21} = 0.48, \quad \text{and} \quad \rho_{22} = 0.45.$$

#### The Profits of Two Firms

$$U_1 = 84.20$$
 and  $U_2 = 1.38$ .

- Consumers differentiate cantaloupes due to food safety and health concerns.
- With the newly designed label, Firm 1 has managed to encourage the consumption of its cantaloupes at both of these two demand markets.

$$d_{11}^* = 17.52, \quad d_{12}^* = 46.46, \quad d_{21}^* = 5.81, \quad \text{and} \quad d_{22}^* = 3.58.$$

#### The Equilibrium Prices

$$\rho_{11} = 2.48, \quad \rho_{12} = 2.99, \quad \rho_{21} = 0.48, \quad \text{and} \quad \rho_{22} = 0.45.$$

#### The Profits of Two Firms

$$U_1 = 84.20$$
 and  $U_2 = 1.38$ .

- Practicing product differentiation may be an effective strategy for a food firm to maintain its profit at an acceptable level.
- Considering the cantaloupe-associated outbreak, it is certainly not easy to reclaim the same profit level as in Case 1.

$$d_{11}^* = 17.52, \quad d_{12}^* = 46.46, \quad d_{21}^* = 5.81, \quad \text{and} \quad d_{22}^* = 3.58.$$

#### The Equilibrium Prices

$$\rho_{11} = 2.48, \quad \rho_{12} = 2.99, \quad \rho_{21} = 0.48, \quad \text{and} \quad \rho_{22} = 0.45.$$

#### The Profits of Two Firms

 $U_1 = 84.20$  and  $U_2 = 1.38$ .

• The demand for Firm 1's product at demand market *R*<sub>1</sub> in Case 3 is even higher than that of Case 1, which is probably caused by the remarkable decrease in the price as well as the introduced guarantee of food safety.

In our research on perishable and time-sensitive product supply chains, we utilize results from physics, chemistry, biology, and medicine in order to capture the perishability of various products over time from food to healthcare products such as blood, medical nucleotides, and pharmaceuticals. A variety of perishable product supply chain models, computational procedures, and applications can be found in our book:

### Supply Chain Networks – Optimization Models

э

A. Nagurney, A. H. Masoumi, and M. Yu, "Supply Chain Network Operations Management of a Blood Banking System with Cost and Risk Minimization," *Computational Management Science* **9(2)** (2012), pp 205-231.

The American Red Cross is the major supplier of blood products to hospitals and medical centers satisfying about 40% of the demand for blood components nationally.

- The shelf life of platelets is **5** days and of red blood cells is **42**.
- Over **39,000** donations are needed everyday in the US, and the blood supply is frequently reported to be just **2** days away from running out (American Red Cross (2010)).
- Some hospitals have delayed surgeries due to blood shortages on **120** days in a year (Whitaker et al. (2007)).
- The national estimate for the number of units blood products outdated by blood centers and hospitals was **1,276,000** out of 15,688,000 units (Whitaker et al. (2007)).
- As of February 1, 2016, the American Red Cross was facing an emergency need for blood and platelet donors. Severe winter weather in January forced the cancellation of more than 340 blood drives in 20 states, resulting in nearly 10,000 donations uncollected. An even more critical situation held in 2018, with also flu being widespread.

#### Supply Chain Network Topology for a Regionalized Blood Bank

ARC Regional Division

Blood Collection Sites

Blood Centers

Component Labs

Storage Facilities

**Distribution Centers** 

**Demand Points** 

We developed a supply chain network optimization model for the management of the procurement, testing and processing, and distribution of a perishable product – that of human blood.

Novel features of the model include:

- It captures perishability of this life-saving product through the use of arc multipliers;
- It contains discarding costs associated with waste/disposal;
- It handles uncertainty associated with demand points;
- It assesses costs associated with shortages/surpluses at the demand points, and
- It quantifies the **supply-side risk** associated with procurement.

# Medical Nuclear Supply Chains

We developed a medical nuclear supply chain network design model which captures the decay of the radioisotope molybdenum.

"Medical Nuclear Supply Chain Design: A Tractable Network Model and Computational Approach," A. Nagurney and L. S. Nagurney, *International Journal of Production Economics* **140(2)** (2012), pp 865-874.

Medical nuclear supply chains are essential supply chains in healthcare and provide the conduits for products used in nuclear medical imaging, which is routinely utilized by physicians for diagnostic analysis for both cancer and cardiac problems.

Such supply chains have unique features and characteristics due to the products' time-sensitivity, along with their hazardous nature.

### **Salient Features:**

- complexity
- economic aspects
- underlying physics of radioactive decay
- importance of considering both waste management and risk management.

Over **100,000** hospitals in the world use radioisotopes (World Nuclear Association (2011)).

Technetium,  ${}^{99m}Tc$ , which is a decay product of Molybdenum-99,  ${}^{99}Mo$ , is the most commonly used medical radioisotope, used in more than 80% of the radioisotope injections, with more than 30 million procedures worldwide each year.

### The half-life of Molybdenum-99 is 66 hours.

Each day, **41,000** nuclear medical procedures are performed in the United States using Technetium-99m.

## Medical Nuclear Supply Chains

A **radioactive isotope** is bound to a pharmaceutical that is injected into the patient and travels to the site or organ of interest in order to construct an image for **medical diagnostic** purposes.

< ロ > < 同 > < 回 > < 回 >

For over two decades, all of the Molybdenum necessary for US-based nuclear medical diagnostic procedures has come from **foreign** sources.

<sup>99</sup>Mo Supply Chain Challenges:

- The majority of the reactors are between **40** and **50** years old. Several of the reactors currently used are due to be retired by the end of this decade (Seeverens (2010) and OECD Nuclear Energy Agency (2010a)).
- Limitations in processing capabilities make the world critically vulnerable to Molybdenum supply chain disruptions.
- The number of generator manufacturers is **under a dozen** (OECD Nuclear Energy Agency (2010b)).
- Long-distance transportation of the product raises safety and security risks, and also results in greater decay of the product.

In 2015, NorthStar Medical Radioisotopes LLC has received approval to begin routine production of molybdenum-99 (Mo-99) at the University of Missouri Research Reactor (MURR) facility in Columbia, Missouri. LEU rather than HEU will be used there.

This transitioning of NorthStar's Mo-99 line at MURR from a development process to a routine production process is another significant step toward establishing a domestic source of Mo-99.

Because of the exponential decay of molybdenum, we have that the quantity of the radioisotope:

$$N(t) = N_0 e^{-\lambda t}$$

so that an arc multiplier on a link a that takes  $t_a$  hours of time corresponds to:

$$\alpha_{\mathbf{a}} = \mathbf{e}^{-\frac{\ln 2}{66.7}t_{\mathbf{a}}}.$$

# Supply Chain Networks - Additional Game Theory Models

글 🖌 🖌 글 🕨

э

### Relationship of the Model to Others in the Literature

The above model is now related to several models in the literature.

If the arc multipliers are all equal to 1, in which case the product is not perishable, then the model is related to the sustainable fashion supply chain network model of Nagurney and Yu in the *International Journal of Production Economics* **135** (2012), pp 532-540. In that model, however, the other criterion, in addition to the profit maximization one, was emission minimization, rather than waste cost minimization, as in the model in this paper.

# Relationship of the Model to Others in the Literature

If the product is homogeneous, and all the arc multipliers are, again, assumed to be equal to 1, and the total costs are assumed to be separable, then the above model collapses to the supply chain network oligopoly model of Nagurney (2010) in which synergies associated with mergers and acquisitions were assessed.

The Original Supply Chain Network Oligopoly Model

Figure: Supply Chain Network Structure of the Oligopoly Without Perishability; Nagurney, *Computational Management Science* **7**(2010), pp 377-401.

## Mergers Through Coalition Formation

Figure: Mergers of the First  $n_{1'}$  Firms and the Next  $n_{2'}$  Firms

э

References can be found in our paper, "A Supply Chain Generalized Network Oligopoly Model for Pharmaceuticals Under Brand Differentiation and Perishability," A.H. Masoumi, M. Yu, and A. Nagurney, *Transportation Research E* **48** (2012), pp 762-780. We consider I pharmaceutical firms, with a typical firm denoted by i.

The firms compete noncooperatively, in an oligopolistic manner, and the consumers can differentiate among the products of the pharmaceutical firms through their individual product brands.

The supply chain network activities include manufacturing, shipment, storage, and, ultimately, the distribution of the brand name drugs to the demand markets.

## Summary

With a focus on such fresh produce items as vegetables and fruits,

- We adopted exponential time decay for the calculation of arc multipliers, so as to handle the discarding of spoiled food products associated with the post-production supply chain activities;
- We considered **product differentiation** due to **product freshness and food safety concerns**; and
- We also allowed for the assessment of alternative technologies involved in each supply chain activity, which could affect the time durations and environmental conditions associated with that activity.
- We related the model to several others in the literature.

Our recent research has returned to food supply chains in which we are also capturing explicit quality deterioration in fresh produce using chemical formulae that capture time and temperature of various supply chain network activities. Some of our applications are to farmers' markets.

In the second part of this lecture, we focus not on perishability in the form of **discarding** of fresh produce but on **the quality deterioration over time based on temperature kinetics**.

We then apply the formalism to an application to Farmers' Markets with a case study on apples in western Massachusetts.

This part of the lecture is based on the paper, "Quality in Competitive Fresh Produce Supply Chains with Application to Farmers' Markets," D. Besik and A. Nagurney, *Socio-Economic Planning Sciences* **60** (2017), pp 62-76. The numbering of the equations, for self-containment in this part of the lecture is: (1), (2), etc.

Even though the transformation of food supply chains from **local to global** is remarkable, there may be some drawbacks.

- Consumers are facing information asymmetry.
- The great distances traveled create issues associated with environmental impact, sustainability, and quality since fresh produce is perishable (Nahmias (2011) and Nagurney et al. (2013)).

We focus on **quality deterioration** through **kinetics** in food supply chains, direct to consumer chains, and, specifically **farmers' markets**.

- Consumers tend to connect the terms 'fresh,' 'good quality,' and 'tasty' with locally produced foods.
- Farmers' markets in **Norway**, have the potential to reduce both physical and social distances between producers and consumers, and, hence, contribute to the sustainability of local food production (Acebo et al.(2007)).
- There were **8,268 farmers' markets** in the United States in 2014, with the number having increased by **180%** since 2006 (USDA(2014)).

• = • •

## **Relevant Literature**

- Various authors have emphasized quality; see Sloof, Tijskens, and Wilkinson (1996), Van der Vorst (2000), Lowe and Preckel (2004), Ahumada and Villalobos (2009, 2011), Blackburn and Scudder (2009), Akkerman, Farahani, and Grunow (2010), and Aiello, La Scalia, and Micale (2012).
- Yu and Nagurney (2013) propose a game theory model for oligopolistic competition in brand differentiated fresh produce supply chains with perishability.
- Tong, Ren, and Mack (2012) propose an optimal site selection model for farmers' markets in Arizona.
- There is limited research on quality decay through kinetics in direct-to-consumer food supply chains.

## What is Quality Decay?

It is difficult to make a globally accepted definition of quality of fresh produce.

Quality of fresh foods can be defined over the combination of their physical attributes such as: color and appearance, flavor, texture, and nutritional value.

An understanding of the biochemical/physicochemical reactions can explain the quality deterioration.

Taoukis and Labuza (1989) explain the rate of quality deterioration of the quality attributes as a function of microenvironment, gas composition, relative humidity, and temperature.

Taoukis and Labuza (1989) and Labuza (1984) show the quality decay of a food attribute Q, over time t, through the differential equation:

$$\frac{-d[Q]}{dt} = k[Q]^n = Ae^{(-E/RT)}[Q]^n, \qquad (1)$$

• where k is the reaction rate defined by the Arrhenius formula:

$$Ae^{(-E/RT)}[Q]^n,$$

- A is the pre-exponential constant, T is temperature, E is activation energy and R is universal gas constant,
- *n* is the reaction order that belongs to the set  $Z^* = \{0\} \cup Z^+$ .

The deterioration function changes with respect to the reaction order of the attribute.

When the initial quality is  $Q_0$ , Tijskens and Polderdijk (1996) categorize the decay functions as:

Reaction Order	Туре	Quality at Time t	
0	Linear	$Q_0 - kt$	
1	Exponential	$Q_0 e^{-kt}$	

Table: Reaction Kinetics and Quality at Time t

Let  $\beta_a$  denote the quality decay incurred on link *a*, which depends on the reaction order *n*, reaction rate  $k_a$  and time  $t_a$  on link *a*, as:

$$\beta_{a} \equiv \begin{cases} -k_{a}t_{a}, & \text{if } n = 0, \forall a \in L \\ e^{-k_{a}t_{a}}, & \text{if } n \neq 0, \forall a \in L. \end{cases}$$
(2)

where

$$k_a = A e^{(-E_A/RT_a)}.$$
 (3)

## Integration of Quality Decay Into the Supply Chain

The quality  $q_p$ , over a path p, joining the origin destination farm, i, with a destination node farmers' market, j, can also be shown as:

$$q_{p} \equiv \begin{cases} q_{0i} + \sum_{a \in p} \beta_{a}, & \text{if } n = 0, \forall a \in L, \ p \in P_{j}^{i}, \forall i, j, \\ \\ q_{0i} \prod_{a \in p} \beta_{a}, & \text{if } n = 1, \forall a \in L, \ p \in P_{j}^{i}, \forall i, j, \end{cases}$$
(4)

- where  $q_{0i}$  is the initial quality of food product at farm *i*,
- $P_j^i$  represents the set of all paths that have origin *i* and destination *j*.

The *I* farms compete **noncooperatively** in an **oligopolistic** manner and the products are differentiated based on **quality** at the farmers' markets.

## The Fresh Produce Supply Chain Topology

- Fixed time horizon in a given season of the fresh fruit or vegetable, typically a week, is assumed.
- **②** The demand points are selected farmers' markets.
- Picking is made right before the time horizon, so that there is no storage for the first farmers' market of the week.
- Onsumers can buy products that are substitutes within or across the demand points.

## The Uncapacitated Fresh Produce Problem

#### Nonnegativity constraint of the path flows

The flow on the path, joining the farm i to the farmers markets k, is denoted by  $x_p$  and it should be nonnegative:

$$x_p \geq 0, \quad \forall p \in P_k^i; i = 1, \dots, I; k = 1, \dots, n_R.$$

#### (5)

#### Link flows

The flow on a link *a* is equal to the sum of the path flows  $x_p$ , on paths that include the link *a*, expressed as:

$$f_{a} = \sum_{p \in P_{k}^{i}} x_{p} \delta_{ap}, \quad \forall a \in L.$$
(6)

#### Demand

The demand at the farmers' market j for the fresh produce product of farmer i is given by:

$$\sum_{p \in P_j^i} x_p = d_{ij}, \quad p \in P_j^i; i = 1, \dots, I; j = 1, \dots, M.$$
(7)

## The Uncapacitated Fresh Produce Problem

#### **Demand Price**

The demand price function  $\rho_{ij}$  for farm  $i{\rm 's}$  product at the farmers' market j, is:

$$\rho_{ij} = \rho_{ij}(d, q), \quad i = 1, \dots, I; j = 1, \dots, M.$$
(8)

#### Link cost

The total operational cost of each link *a*, denoted by  $\hat{c}_a$ , depends on the flows on all the links in the fresh produce supply chain network, that is,

$$\hat{c}_a = \hat{c}_a(f), \quad \forall a \in L,$$
 (9)

#### Profit/Utility

The profit/utility function of farm *i*, denoted by  $U_i$ , is given by:

$$U_{i} = \sum_{j=1}^{M} \rho_{ij}(d,q) d_{ij} - \sum_{a \in L^{i}} \hat{c}_{a}(f).$$
(10)

Definition: Fresh Produce Supply Chain Network Cournot-Nash Equilibrium for Farmers' Markets in the Uncapacitated Case

A path flow pattern  $X^* \in K = \prod_{i=1}^{l} K_i$  constitutes a fresh produce supply chain network Cournot-Nash equilibrium if for each farm *i*; *i* = 1,...,*l*:

$$\hat{U}_i(X_i^*, \hat{X}_i^*) \geq \hat{U}_i(X_i, \hat{X}_i^*), \quad \forall X_i \in K_i,$$
 (11)

where  $\hat{X}_{i}^{*} \equiv (X_{1}^{*}, \dots, X_{i-1}^{*}, X_{i+1}^{*}, \dots, X_{I}^{*})$  and  $K_{i} \equiv \{X_{i} | X_{i} \in R_{+}^{n_{Pi}}\}.$ 

• A Cournot-Nash Equilibrium is established if no farm can unilaterally improve its profit by changing its product flows throughout its supply chain network, given the product flow decisions of the other farms.

## Theorem: Variational Inequality Formulations of the Uncapacitated Model

 $X^* \in K$  is a fresh produce supply chain network Cournot-Nash equilibrium for farmers' markets according to the Definition if and only if it satisfies the variational inequality:

$$-\sum_{i=1}^{I} \langle \nabla_{X_i} \hat{U}_i(X^*), X_i - X_i^* \rangle \ge 0, \quad \forall X \in \mathcal{K},$$
(12)

where  $\langle \cdot, \cdot \rangle$  denotes the inner product in the corresponding Euclidean space and  $\nabla_{X_i} \hat{U}_i(X)$  denotes the gradient of  $\hat{U}_i(X)$  with respect to  $X_i$ .

a∈Li b∈Li

The variational inequality for our uncapacitated model is equivalent to the variational inequality that determines the vector of equilibrium path flows  $x^* \in K^1$  such that:

$$\sum_{i=1}^{I} \sum_{j=1}^{M} \sum_{p \in P_{j}^{i}} \left[ \frac{\partial \hat{\mathcal{C}}_{p}(x^{*})}{\partial x_{p}} - \hat{\rho}_{ij}(x^{*}, q) - \sum_{l=1}^{M} \frac{\partial \hat{\rho}_{il}(x^{*}, q)}{\partial x_{p}} \sum_{r \in P_{l}^{i}} x_{r}^{*} \right] \times [x_{p} - x_{p}^{*}] \ge 0, \, \forall x \in \mathcal{K}^{1},$$
where  $\mathcal{K}^{1} \equiv \{x | x \in \mathcal{R}^{n_{p}}_{+}\}$ , and for each path  $p; \, p \in P_{j}^{i}; \, i = 1, \dots, I; \, j = 1, \dots, M,$ 

$$\frac{\partial \hat{\mathcal{C}}_{p}(x)}{\partial x_{p}} \equiv \sum_{r \in \mathcal{L}_{i}} \sum_{l \in I \in \mathcal{L}_{i}} \frac{\partial \hat{\mathcal{C}}_{b}(f)}{\partial f_{a}} \delta_{ap} \text{ and } \frac{\partial \hat{\rho}_{il}(x, q)}{\partial x_{p}} \equiv \frac{\partial \rho_{il}(d, q)}{\partial d_{ij}}.$$
(14)

## The Uncapacitated Fresh Produce Problem

The variational inequality can also be rewritten in terms of link flows as: determine the vector of equilibrium link flows and the vector of equilibrium demands  $(f^*, d^*) \in K^2$ , such that:

$$\sum_{i=1}^{I} \sum_{a \in L^{i}} \left[ \sum_{b \in L^{i}} \frac{\partial \hat{c}_{b}(f^{*})}{\partial f_{a}} \right] \times [f_{a} - f_{a}^{*}]$$

$$+ \sum_{i=1}^{I} \sum_{j=1}^{M} \left[ -\rho_{ij}(d^{*}, q) - \sum_{l=1}^{M} \frac{\partial \rho_{il}(d^{*}, q)}{\partial d_{ik}} d_{il}^{*} \right] \times [d_{ij} - d_{ij}^{*}] \ge 0, \forall (f, d) \in K^{2},$$

$$(15)$$
where  $K^{2} \equiv \{(f, d) | x \ge 0, and (6) and (7) hold\}.$ 

 Proof: (12) follows from Gabay and Moulin (1980); see, also, Masoumi, Yu, and Nagurney (2012). (13) and (15) then follow using algebraic substitutions. □ Variational inequalities (13) and (15) can be put into standard form (see Nagurney (1999)): determine  $X^* \in \mathcal{K}$  such that:

$$\langle F(X^*), X - X^* \rangle \ge 0, \quad \forall X \in \mathcal{K},$$
 (16)

where  $\langle \cdot, \cdot \rangle$  denotes the inner product in *N*-dimensional Euclidean space with  $N = n_P$  in our model. Let  $X \equiv x$  and

$$F(X) \equiv \left[\frac{\partial \hat{C}_{p}(x)}{\partial x_{p}} - \hat{\rho}_{ij}(x,q) - \sum_{l=1}^{M} \frac{\partial \hat{\rho}_{il}(x,q)}{\partial x_{p}} \sum_{r \in P_{l}^{i}} x_{r};\right]$$
$$p \in P_{j}^{i}; i = 1, \dots, l; j = 1, \dots, M \right],$$
(17)

and  $\mathcal{K} \equiv \mathcal{K}^1$ , then (10) can be re-expressed as (13).

## The Capacitated Fresh Produce Problem

- Labor shortages, weather conditions, disruptions to storage or transportation can limit the supply chain activities.
- The objective function, the constraints, with conservation of flow equations stay the same.

#### Link capacity constraint

$$f_a \leq u_a, \quad \forall a \in L,$$
 (20a)

$$\sum_{p \in P} x_p \delta_{ap} \le u_a, \quad \forall a \in L,$$
(20b)

where  $K_i^3 \equiv \{X_i | X_i \in R_+^{n_{pi}} \text{ and } (20b) \text{ holds for } a \in L^i\}$  and  $K^3 \equiv \prod_{i=1}^{l} K_i^3$ .

The variational inequality is equivalent to the variational inequality problem: determine  $(x^*, \lambda^*) \in K^4$ , where  $K^4 \equiv \{x \in R^{n_P}_+, \lambda \in R^{n_L}_+\}$ , such that:

$$\sum_{i=1}^{l} \sum_{j=1}^{M} \sum_{p \in P_j^i} \left[ \frac{\partial \hat{\mathcal{C}}_p(x^*)}{\partial x_p} - \hat{\rho}_{ij}(x^*, q) - \sum_{l=1}^{M} \frac{\partial \hat{\rho}_{il}(x^*, q)}{\partial x_p} \sum_{r \in P_l^i} x_r^* + \sum_{a \in L} \lambda_a^* \delta_{ap} \right] \times [x_p - x_p^*]$$

$$+\sum_{a\in L}\left[u_a-\sum_{p\in P}x_p^*\delta_{ap}\right]\times[\lambda_a-\lambda_a^*]\geq 0,\quad\forall (x,\lambda)\in K^4,$$
(21)

where 
$$\frac{\partial \hat{C}_{p}(x)}{\partial x_{p}}$$
 and  $\frac{\partial \hat{\rho}_{il}(x,q)}{\partial x_{p}}$  are as defined in (14).

Closed form expressions for the fresh produce path flows, for each path  $p \in P_i^i$ ,  $\forall i, j$ :

$$\begin{aligned} x_{p}^{\tau+1} &= \max\{0, x_{p}^{\tau} + a_{\tau}(\hat{\rho}_{ij}(x^{\tau}, q) + \sum_{l=1}^{M} \frac{\partial \hat{\rho}_{il}(x^{\tau}, q)}{\partial x_{p}} \sum_{r \in P_{l}^{i}} x_{r}^{\tau} - \frac{\partial \hat{C}_{p}(x^{\tau})}{\partial x_{p}})\}, \\ \forall p \in P_{j}^{i}; \ i = 1, \dots, I; \ j = 1, \dots, M. \end{aligned}$$

$$(23)$$

# The Euler Method Explicit Formulae for the Capacitated Model

For each path  $p \in P_i^i$ ,  $\forall i, j$ , compute:

$$x_{p}^{\tau+1} = \max\{0, x_{p}^{\tau} + a_{\tau}(\hat{\rho}_{ij}(x^{\tau}, q) + \sum_{l=1}^{M} \frac{\partial \hat{\rho}_{il}(x^{\tau}, q)}{\partial x_{p}} \sum_{r \in P_{l}^{i}} x_{r}^{\tau} - \frac{\partial \hat{C}_{p}(x^{\tau})}{\partial x_{p}} - \sum_{a \in L} \lambda_{a}^{\tau} \delta_{ap})\},$$

$$\forall p \in P_{j}^{i}; i = 1, \dots, I; j = 1, \dots, M.$$

$$(24)$$

The Lagrange multipliers for each link  $a \in L^i$ ; i = 1, ..., I, compute:

$$\lambda_a^{\tau+1} = \max\{0, \lambda_a^{\tau} + a_{\tau}(\sum_{p \in P} x_p^{\tau} \delta_{ap} - u_a)\}, \ \forall a \in L.$$
(25)

## Case Study of Apple Orchards in Western Massachusetts

#### Orchard/farms:

- Apex Orchards are located in Shelburne Falls.
- Park Hill Orchard is located in Easthampton.
- Sentinel Farm is located in Belchertown.

#### Farmers' markets:

- Northampton Farmers' Market is open on Tuesdays.
- South Hadley Farmers' Market is open on Thursdays.
- Amherst Farmers' Market is open on Saturdays.
- Belchertown Farmers' Market is open on Sundays.

## Scenario 1 - Some Information

- Picking is made on Monday; therefore, there are no storage links for the Northampton Farmers' Market.
- Golden Delicious apples follow first order quality decay.
- Harvesting is made between September and October, with average temperatures 19-22 C°.

(日) (同) (三) (三)

## Scenario 1 - Some Information

- Apex Orchards have the largest land size (170 acres), followed by Park Hill Orchard (127 acres) and Sentinel Farm (8 acres).
- Apex is located in a higher altitude, so that the average harvesting temperature at the orchard is lower than others.
- Apex uses controlled atmosphere storage which maintains the optimal temperature, 0  $C^{\circ}$ .
- We assume that orchard/farm *i*; i = 1, 2, 3, in the supply chain network has initial quality, respectively, of:  $q_{01} = 1$ ,  $q_{02} = 0.8$ , and  $q_{03} = 0.7$ .
- Uncapacitated model is used.

Apex Orchards' price of apples per peck:

 $\rho_{11} = 27.33, \quad \rho_{12} = 24.53, \quad \rho_{13} = 30.72, \quad \rho_{14} = 25.42,$ 

### Park Hill Orchard's price of apples per peck:

 $\rho_{21} = 21.25, \quad \rho_{22} = 26.13, \quad \rho_{23} = 26.34, \quad \rho_{24} = 27.40,$ 

### Sentinel Farm's price of apples per peck:

$$\rho_{31} = 20.79, \quad \rho_{32} = 25.16, \quad \rho_{33} = 24.29, \quad \rho_{34} = 24.50.$$

Profits of the orchard/farms, in dollars:

 $U_1(X^*) = 1785.40, \quad U_2(X^*) = 484.03, \quad U_3(X^*) = 460.15.$ 

### Scenario 2 - Some Information

• It is assumed that a new orchard, which was solely selling to retailers and wholesalers previously, is attracted by the demand for apples at the farmers' markets.

- It has similar orchard characteristics to Apex Orchards.
- It is located in **Belchertown**, which has similar seasonal temperatures to the other farm/orchards.
- The transportation time from the New Orchard to the farmers' markets is similar to Sentinel Farm.

Apex Orchards' price of apples per peck:

$$\rho_{11} = 23.49, \quad \rho_{12} = 23.66, \quad \rho_{13} = 27.49, \quad \rho_{14} = 24.44,$$

Park Hill Orchard's price of apples per peck:

$$\rho_{21} = 21.46, \quad \rho_{22} = 25.41, \quad \rho_{23} = 25.49, \quad \rho_{24} = 26.20,$$

Sentinel Farm's price of apples per peck:

$$\rho_{31} = 20.38, \quad \rho_{32} = 24.38, \quad \rho_{33} = 22.91, \quad \rho_{34} = 23.08,$$

New Orchard's price of apples per peck:

$$\rho_{41} = 23.82, \quad \rho_{42} = 23.99, \quad \rho_{43} = 27.80, \quad \rho_{44} = 24.21.$$

Profits of the orchard/farms, in dollars:

$$U_1(X^*) = 1097.39, U_2(X^*) = 471.71,$$

$$U_3(X^*) = 345.45, U_4(X^*) = 1142.19.$$

## Scenario 3 - Some Information

- This scenario is constructed to illustrate the apple shortage experienced in western Massachusetts in 2016.
- According to various news articles, the cold snap happened in May damaged the green apple buds and an apple shortage at the local markets, which includes the farmers' markets, is expected.
- Expected shortage is assumed to **be more for Apex** due to being located in a **higher altitude**.
- The capacities are written according to the **expected damage level of the harvest** at the orchard/farms.
- Initial quality of the apples in the orchards is  $q_{01} = 0.4$ ,  $q_{02} = 0.5$ , and  $q_{03} = 0.6$ .

- In the second part of this lecture, we provided **explicit formulae** for quality deterioration and found the quality associated with every path in the network.
- We focused on **farmers' markets** which are direct to consumer chains.
- We provided a **game theory model** for **supply chain** competition in a network framework for farmers' markets.
- This is the **first work** in the literature with a supply chain game theory model for farmers' markets with **quality deterioration**.
