I'd like to thank Dr. Les Servi for the invitation to speak with you.

I acknowledge support for some of the research in this presentation provided by the **Advanced Cyber Security Center (ACSC)** and the **National Science Foundation (NSF)** through the project: Collaborative Research: Network Innovation Through Choice, which envisions a Future Internet Architecture.

Special acknowledgments and thanks to my students and collaborators who have made research and teaching always stimulating and rewarding.

Background and Motivation

How I Became Interested in Cybersecurity

One of my books, written with a UMass Amherst alum, was “hacked” and digital copies of it posted on websites around the globe.

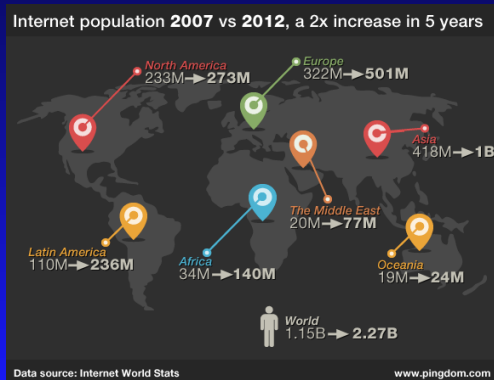

In a sense, this may be viewed as a compliment since clearly someone had determined that it has some sort of *value*.

The publisher John Wiley & Sons was notified and lawyers got involved but how do you contact and then influence those responsible for postings on rather anonymous websites?

About the same time news about cyberattacks was getting prominent attention in the media and there were those interested in working with us on related research on cybersecurity.

The Internet has transformed the ways in which individuals, groups, organizations communicate, obtain information, access entertainment, and conduct their economic and social activities.

70% of households and 94% of businesses with 10 or more employees are online with an immense growth in mobile devices and social media. In 2012, there were over 2.4 billion users. In 2015, there were 3 billion users, almost half of the world population

The Cost of Cybercrime

According to the Center for Strategic and International Studies (2014), the world economy sustained \$445 billion in losses from cyberattacks in 2014. The United States suffered a loss of \$100 billion, Germany lost \$60 billion, China lost \$45 billion, and the United Kingdom reported a loss of \$11.4 billion due to cybersecurity lapses.

The think tank also presented an analysis that indicated that of the \$2 trillion to \$3 trillion generated by the Internet annually, about 15%-20% is extracted by cybercrime.

Cybercrime

- **Cybercrimes are costly for organizations.** The Ponemon Institute (2015) reports that the average annualized cost of cybercrime incurred by a benchmark sample of organizations was \$15 million. The range of these annualized costs was \$1.9 million to \$65 million, an 82% increase in the past six years.

Cybercrime

- **Cybercrimes are costly for organizations.** The Ponemon Institute (2015) reports that the average annualized cost of cybercrime incurred by a benchmark sample of organizations was \$15 million. The range of these annualized costs was \$1.9 million to \$65 million, an 82% increase in the past six years.
- **All industries fall victim to cybercrime, but to different degrees with defense, energy and utilities, and financial service companies** experiencing higher cybercrime costs than organizations in retail, hospitality, and consumer products.

Cybercrime

In 2014 alone, Target, Home Depot, Michaels Stores, Staples, and eBay were breached. Card data and personal information of millions of customers were stolen and the detection of cyber espionage became the prime focus for the retail sector with regards to cybersecurity (The New York Times (2015)).

Since financial gains are one of the most attractive benefits emerging from cyberattacks, financial service firms are targeted incessantly.

The large-scale data breach of JP Morgan Chase, Kaspersky Lab's detection of a two-year infiltration of 100 banks across the world costing \$1 billion (USA Today (2015)), and the Dridex malware related losses of \$100 million worldwide (The Guardian (2015)) are some of the widely accepted cautionary tales in this sector.

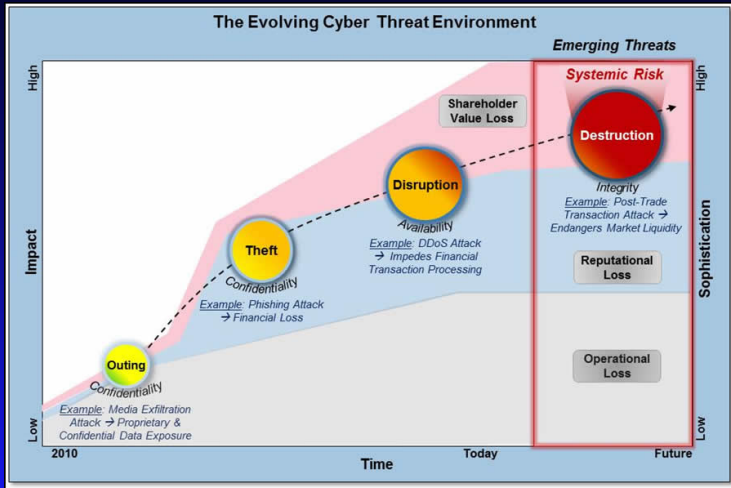

Cybercrime

More than 76 million households and seven million small businesses were compromised because of JP Morgan attacks.

Clearly, hackers go where there is money.

The most costly cybercrimes (58% annually) are those caused by denial of service, malicious insider and web-based attacks. Mitigation may require enabling technologies, intrusion prevention systems, applications security testing solutions and enterprise solutions.

Cyberattacks

Every minute, of every hour, of ever day, a major financial institution is under attack (Wilson in *The Telegraph*, October 6, 2013).

Preparation, prediction, and protection are key - which are the weakest links?

Cybercrime and Financial Institutions

According to a recent survey cybercrime is placing heavy strains on the global financial sector, with cybercrime now the second most commonly reported economic crime affecting financial services firms.

Cybercrime and Financial Institutions

According to a recent survey cybercrime is placing heavy strains on the global financial sector, with cybercrime now the second most commonly reported economic crime affecting financial services firms.

Cybercrime accounted for 38% of all economic crimes in the financial sector, as compared to an average of 16% across all other industries.

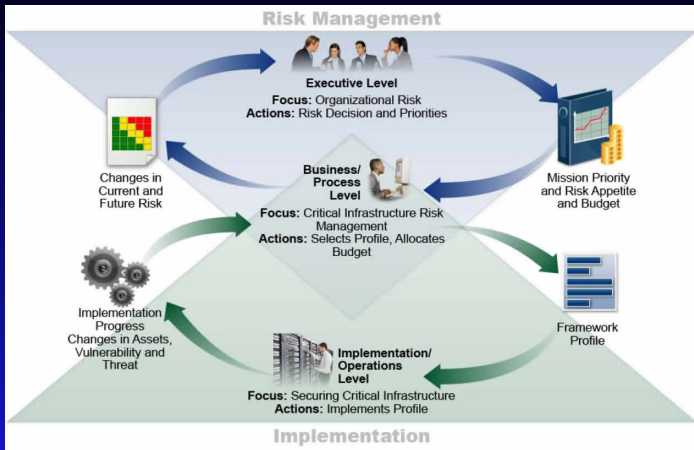

Cybercrime and Financial Institutions

According to a recent survey cybercrime is placing heavy strains on the global financial sector, with cybercrime now the second most commonly reported economic crime affecting financial services firms.

Cybercrime accounted for 38% of all economic crimes in the financial sector, as compared to an average of 16% across all other industries.

Cyberattacks are intrusive and economically costly. In addition, they may adversely affect a company's most valuable asset its reputation.

It's About Risk Management

Networks and Behavior

Our enterprises and organizations are critically dependent on infrastructure network systems including the Internet.

Behavior on Congested Networks

Decision-makers select their cost-minimizing routes.

Flows are routed so as to minimize total cost to society.

Two fundamental principles of travel behavior, due to Wardrop (1952), with terms coined by Dafermos and Sparrow (1969).

User-optimized (U-O) (network equilibrium) Problem – each user determines his/her cost minimizing route of travel between an origin/destination, until an equilibrium is reached, in which no user can decrease his/her cost of travel by unilateral action (in the sense of Nash).

System-optimized (S-O) Problem – users are allocated among the routes so as to minimize the total cost in the system, where the total cost is equal to the sum over all the links of the link's user cost times its flow.

The U-O problems, under certain simplifying assumptions, possesses optimization reformulations. But now we can handle cost asymmetries, multiple modes of transport, and different classes of travelers, without such assumptions.

We Can State These Conditions Mathematically!

The U-O and S-O Conditions

Definition: U-O or Network Equilibrium – Fixed Demands

A path flow pattern x^* , with nonnegative path flows and O/D pair demand satisfaction, is said to be U-O or in equilibrium, if the following condition holds for each O/D pair $w \in W$ and each path $p \in P_w$:

$$C_p(x^*) \begin{cases} = \lambda_w, & \text{if } x_p^* > 0, \\ \geq \lambda_w, & \text{if } x_p^* = 0. \end{cases}$$

Definition: S-O Conditions

A path flow pattern x with nonnegative path flows and O/D pair demand satisfaction, is said to be S-O, if for each O/D pair $w \in W$ and each path $p \in P_w$:

$$\hat{C}'_p(x) \begin{cases} = \mu_w, & \text{if } x_p > 0, \\ \geq \mu_w, & \text{if } x_p = 0, \end{cases}$$

where $\hat{C}'_p(x) = \sum_{a \in \mathcal{L}} \frac{\partial \hat{c}_a(f_a)}{\partial f_a} \delta_{ap}$, and μ_w is a Lagrange multiplier.

The importance of behavior will now be illustrated through a famous example known as the Braess paradox which demonstrates what can happen under *U-O* as opposed to *S-O* behavior.

Although the paradox was presented in the context of transportation networks, it is relevant to other network systems in which decision-makers act in a noncooperative (competitive) manner.

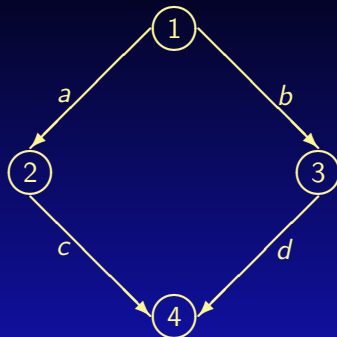

The Braess (1968) Paradox

Assume a network with a single O/D pair (1,4). There are 2 paths available to travelers: $p_1 = (a, c)$ and $p_2 = (b, d)$.

For a travel demand of **6**, the equilibrium path flows are $x_{p_1}^* = x_{p_2}^* = 3$ and

The equilibrium path travel cost is

$$C_{p_1} = C_{p_2} = 83.$$

$$c_a(f_a) = 10f_a, \quad c_b(f_b) = f_b + 50,$$

$$c_c(f_c) = f_c + 50, \quad c_d(f_d) = 10f_d.$$

Adding a Link Increases Travel Cost for All!

Adding a new link creates a new path $p_3 = (a, e, d)$.

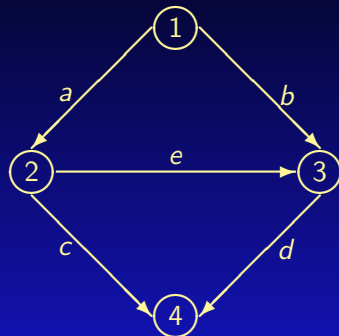

The original flow distribution pattern is no longer an equilibrium pattern, since at this level of flow the cost on path p_3 , $C_{p_3} = 70$.

The new equilibrium flow pattern network is

$$x_{p_1}^* = x_{p_2}^* = x_{p_3}^* = 2.$$

The equilibrium path travel cost:

$$C_{p_1} = C_{p_2} = C_{p_3} = 92.$$

$$c_e(f_e) = f_e + 10$$

The 1968 Braess article has been translated from German to English and appears as:

On a Paradox of Traffic Planning,

Transportation Science 39 (2005), pp 446-450.

Über ein Paradoxon aus der Verkehrsplanung

Von D. Braess, Münster¹⁾

Erschienen am 28. März 1968

Zusammenfassung: Für die Straßenverkehrsplanung stellen sich dem Verkehrsfuß auf den meisten Straßen die beiden Aufgaben, einerseits die Zeit für den Verkehr zu minimieren, andererseits die Kosten zu minimieren. Beide Ziele sind gegensätzlich, und es ist zu erwarten, dass die beiden Ziele nicht gleichzeitig erreicht werden können. Es ist zu erwarten, dass die beiden Ziele nicht gleichzeitig erreicht werden können. Es ist zu erwarten, dass die beiden Ziele nicht gleichzeitig erreicht werden können.

Abstract: For the traffic planning, the two main tasks of the traffic planning are to minimize the time for the traffic and to minimize the costs. Both tasks are contradictory, and it is to be expected that the two tasks cannot be achieved simultaneously. It is to be expected that the two tasks cannot be achieved simultaneously. It is to be expected that the two tasks cannot be achieved simultaneously.

1. Einführung

Für die Verkehrsplanung und Verkehrsplanung nimmt sich die Verkehrsplanung auf die einzelnen Straßen des Verkehrsnetzes vor. Bekannt ist dabei die Anzahl der Fahrzeuge für alle Ausgange- und Zufahrten. Die der Berechnung wird davon ausgegangen, daß von den möglichen Wegen jeweils der günstigste gewählt wird. Wie günstig ein Weg ist, richtet sich nach dem Aufwand, der zum Durchfahren nötig ist. Die Grundlage für die Berechnung des Aufwandes bildet die Fahrzeit.

Für die mathematische Behandlung wird das Straßennetz durch einen gerichteten Graphen beschrieben. Der Charakterisierung der Bögen gehört die Angabe des Zeitaufwandes. Die Bestimmung der günstigsten Streckenrichtungen kann als gelöst betrachtet werden, wenn die Berechnung korrekt ist, d. h., wenn die Fahrzeiten unabhängig von der Größe des Verkehrsnetzes sind. Sie ist dann äquivalent mit der bekannten Aufgabe, den kürzesten Abstand zwischen Punkten eines Graphen und dem zugehörigen kürzesten Pfad zu bestimmen [1, 2].

Will man das Modell aber realistisch gestalten, ist zu berücksichtigen, daß die benötigte Zeit stark von der Größe des Verkehrsnetzes abhängt. Wie die folgenden Untersuchungen zeigen, ergeben sich dann ganz andere Modelle mit konstanter Durchgangsfähigkeit. Bekannt ist, daß eine Straße nur so viele Fahrzeuge gleichzeitig aufnehmen kann, wie sie aufnehmen kann. Es ist zu erwarten, dass die beiden Ziele nicht gleichzeitig erreicht werden können. Es ist zu erwarten, dass die beiden Ziele nicht gleichzeitig erreicht werden können.

Abstract: For the traffic planning, the two main tasks of the traffic planning are to minimize the time for the traffic and to minimize the costs. Both tasks are contradictory, and it is to be expected that the two tasks cannot be achieved simultaneously. It is to be expected that the two tasks cannot be achieved simultaneously. It is to be expected that the two tasks cannot be achieved simultaneously.

1. Introduction

The task of the traffic planning is to minimize the time for the traffic and to minimize the costs. Both tasks are contradictory, and it is to be expected that the two tasks cannot be achieved simultaneously. It is to be expected that the two tasks cannot be achieved simultaneously. It is to be expected that the two tasks cannot be achieved simultaneously.

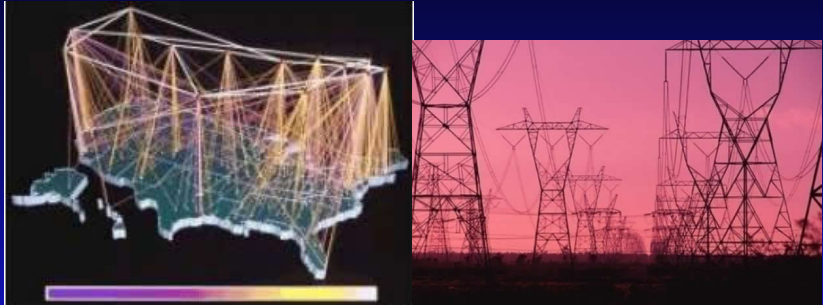

For the traffic planning, the two main tasks of the traffic planning are to minimize the time for the traffic and to minimize the costs. Both tasks are contradictory, and it is to be expected that the two tasks cannot be achieved simultaneously. It is to be expected that the two tasks cannot be achieved simultaneously. It is to be expected that the two tasks cannot be achieved simultaneously.

Will man das Modell aber realistisch gestalten, ist zu berücksichtigen, daß die benötigte Zeit stark von der Größe des Verkehrsnetzes abhängt. Wie die folgenden Untersuchungen zeigen, ergeben sich dann ganz andere Modelle mit konstanter Durchgangsfähigkeit. Bekannt ist, daß eine Straße nur so viele Fahrzeuge gleichzeitig aufnehmen kann, wie sie aufnehmen kann. Es ist zu erwarten, dass die beiden Ziele nicht gleichzeitig erreicht werden können. Es ist zu erwarten, dass die beiden Ziele nicht gleichzeitig erreicht werden können.

Under S-O behavior, the total cost in the network is minimized, and the new route p_3 , under the same demand, would not be used.

The Braess paradox never occurs in S-O networks.

The Financial Network Model

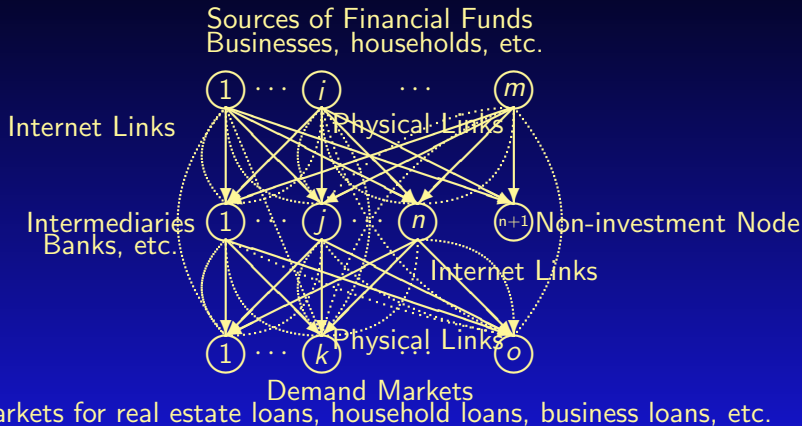

Figure 1: The Structure of the Financial Network with Intermediation

The Nagurney and Qiang (N-Q) Network Performance Measure

Definition: A Unified Network Performance Measure

The network performance/efficiency measure, $\mathcal{E}(G, d)$, for a given network topology G and the equilibrium (or fixed) demand vector d , is:

$$\mathcal{E} = \mathcal{E}(G, d) = \frac{\sum_{w \in W} \frac{d_w}{\lambda_w}}{n_W},$$

where recall that n_W is the number of O/D pairs in the network, and d_w and λ_w denote, for simplicity, the equilibrium (or fixed) demand and the equilibrium disutility for O/D pair w , respectively.

Anna Nagurney and Qiang Qiang, A Network Efficiency Measure with Application to Critical Infrastructure Networks, *Journal of Global Optimization* 40 (2008), pp 261-275.

The Importance of Nodes and Links

Definition: Importance of a Network Component

The importance of a network component $g \in G$, $I(g)$, is measured by the relative network efficiency drop after g is removed from the network:

$$I(g) = \frac{\Delta \mathcal{E}}{\mathcal{E}} = \frac{\mathcal{E}(G, d) - \mathcal{E}(G - g, d)}{\mathcal{E}(G, d)}$$

where $G - g$ is the resulting network after component g is removed from network G .

Approach to Identifying the Importance of Network Components

The elimination of a link is treated in the N-Q network efficiency measure by removing that link while the removal of a node is managed by removing the links entering and exiting that node.

In the case that the removal results in no path connecting an O/D pair, we simply assign the demand for that O/D pair to an abstract path with a cost of infinity.

The N-Q measure is well-defined even in the case of disconnected networks.

The Ranking of Links in the Braess Network

Table 1: Link Results for the Braess Network

Link	N-Q Measure		L-M Measure	
	Importance Value	Importance Ranking	Importance Value	Importance Ranking
<i>a</i>	.2069	1	.1056	3
<i>b</i>	.1794	2	.2153	2
<i>c</i>	.1794	2	.2153	2
<i>d</i>	.2069	1	.1056	3
<i>e</i>	-.1084	3	.3616	1

N-Q (Nagurney-Qiang); L-M (Latora-Marchiori)

The Ranking of Nodes in the Braess Network

Table 2: Nodal Results for the Braess Network

Node	N-Q Measure		L-M Measure	
	Importance Value	Importance Ranking	Importance Value	Importance Ranking
1	1.0000	1	—	—
2	.2069	2	.7635	1
3	.2069	2	.7635	1
4	1.0000	1	—	—

Advantages of the N-Q Network Efficiency Measure

- The measure captures *demands, flows, costs, and behavior of users*, in addition to *network topology*.
- The resulting importance definition of network components is applicable and *well-defined even in the case of disconnected networks*.
- It can be used to identify the *importance (and ranking) of either nodes, or links, or both*.
- It can be applied to *assess the efficiency/performance of a wide range of network systems, including financial systems and supply chains under risk and uncertainty*.
- It is applicable also to *elastic demand networks*.
- It is *applicable to dynamic networks, including the Internet*.

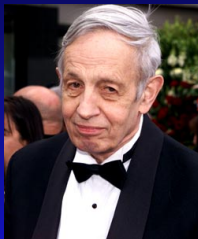

Financial Networks and Game Theory

Game Theory

Game Theory

There are many game theory problems and tools for solving such problems. There is noncooperative game theory, in which the players or decision-makers compete with one another, and cooperative game theory, in which players cooperate with one another.

John F. Nash

In **noncooperative games**, the governing concept is that of Nash equilibrium. In **cooperative games**, we can apply Nash bargaining theory.

Game Theory

Game theory is very useful.

In order to set up a game theory model, you need to identify the players, their strategic variables (strategies), the constraints on their strategies, and their pay-off functions.

Pay-off functions can be profit functions, for example.

A Network Economic Model of Cybercrime

Network Economics of Cybercrime

We lay the foundation for the development of network economics based models for cyberccrime in financial services.

Financial services firms as well as hackers are economic agents.

Our view is that financial firms produce/possess commodities (or products) that hackers (criminals) seek to obtain.

We assume that the firms (as well as the hackers) can be located in different regions of a country or in different countries. Financial service firms may also be interpreted as prey and the hackers as predators.

Network Economics of Cybercrime

Commodities or products that the hackers seek to acquire may include: credit card numbers, password information, specific documents, etc.

The financial firms are the producers of these commodities whereas the hackers act as agents and “sell” these products, if they acquire them, at the “going” market prices.

There is a “price” at which the hackers acquire the financial commodity from a financial institution and a price at which they sell the hacked product in the demand markets. The former we refer to as the supply price and the latter is the demand price.

Network Economics of Cybercrime

In addition, we assume that there is a transaction cost associated between each pair of financial and demand markets for each commodity. These transaction costs can be generalized costs that also capture risk.

Network Economics of Cybercrime

Indeed, if the cyber criminals do not find demand markets for their acquired financial commodities (since there are no consumers willing to pay the price) then there is no economic incentive for them to acquire the financial commodities.

Network Economics of Cybercrime

Indeed, if the cyber criminals do not find demand markets for their acquired financial commodities (since there are no consumers willing to pay the price) then there is no economic incentive for them to acquire the financial commodities.

To present another criminal network analogue – consider the market for illegal drugs, with the U.S. market being one of the largest, if not the largest one. If there is no demand for the drugs then the suppliers of illegal drugs cannot recover their costs of production and transaction and the flows of drugs will go to zero.

Network Economics of Cybercrime

Indeed, if the cyber criminals do not find demand markets for their acquired financial commodities (since there are no consumers willing to pay the price) then there is no economic incentive for them to acquire the financial commodities.

To present another criminal network analogue – consider the market for illegal drugs, with the U.S. market being one of the largest, if not the largest one. If there is no demand for the drugs then the suppliers of illegal drugs cannot recover their costs of production and transaction and the flows of drugs will go to zero.

According to a recent Rand report, for many, the cyber black market can be more profitable than the illegal drug trade.

Network Economics of Cybercrime

- After the major Target breach, credit cards obtained thus initially sold for \$120 each on the black market, but, within weeks, as banks started to cancel the cards, the price dropped to \$8 and, seven months after Target learned about the breach, the cards had essentially no value.

Network Economics of Cybercrime

- After the major Target breach, credit cards obtained thus initially sold for \$120 each on the black market, but, within weeks, as banks started to cancel the cards, the price dropped to \$8 and, seven months after Target learned about the breach, the cards had essentially no value.
- In addition, different brands of credit cards can be viewed as different products since they command different prices on the black market. For example, according to Leinwand Leger (2014) credit cards with the highest credit limits, such as an American Express Platinum card, command the highest prices.

Network Economics of Cybercrime

- After the major Target breach, credit cards obtained thus initially sold for \$120 each on the black market, but, within weeks, as banks started to cancel the cards, the price dropped to \$8 and, seven months after Target learned about the breach, the cards had essentially no value.
- In addition, different brands of credit cards can be viewed as different products since they command different prices on the black market. For example, according to Leinwand Leger (2014) credit cards with the highest credit limits, such as an American Express Platinum card, command the highest prices.
- A card number with a low limit might sell for \$1 or \$2, while a high limit card number can sell for \$15 or considerably more, as noted above. Hacked credit card numbers of European credit cards can command prices five times higher than U.S. cards (see Peterson (2013)).

Perishability and Cybercrime in Financial Products

There is a short time window during which the value of a financial product acquired through cybercrime is positive but it decreases during the time window. Hence, financial products such as credit cards that are hacked can be treated as perishable products such as fruits, vegetables, etc.

Perishability and Cybercrime in Financial Products

This part of the presentation is based on the paper, A Multiproduct Network Economic Model of Cybercrime in Financial Services, Anna Nagurney, *Service Science* 7(1) (2015) pp 70-81.

Perishability and Cybercrime in Financial Products

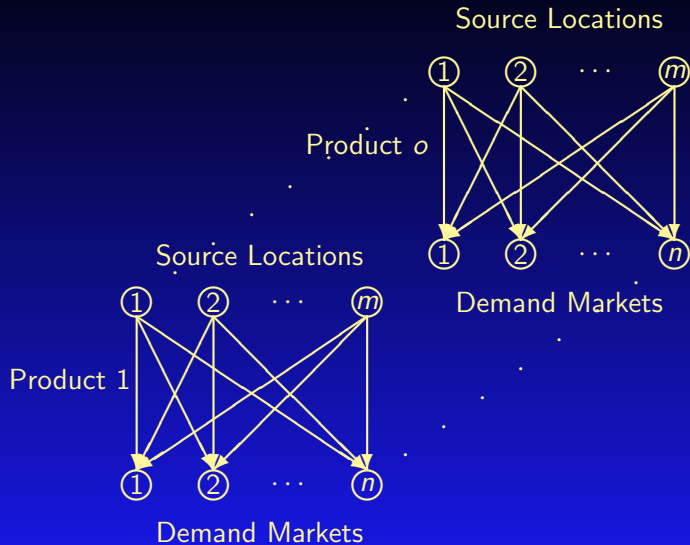

Figure 2: Structure of the Network Economic Problem

Some Notation - Variables

Let Q_{ij}^k denote the nonnegative amount of financial product k obtained from i and shipped to j .

Let s_i^k denote the nonnegative supply of financial product k at i and let d_j^k be the demand for k at j .

T_{ij}^k is the time between the acquisition of product k from source location i and its sale at j .

$T_{ave,j}^k$ is the average time for delivery of product k at demand market j , where
$$T_{ave,j}^k = \frac{\sum_{i=1}^m T_{ij}^k Q_{ij}^k}{d_j^k}.$$

Some Notation - Functions

Let $\pi_i^k(s)$ denote the price of acquiring product k at source location i .

Let $\rho_j^k(d, T_{ave})$ denote the demand price of financial product k at demand market j .

Let $\hat{c}_{ij}^k(Q)$ denote the unit transaction cost associated with transacting product k between i and j .

Conservation of Flow Equations

The conservation of flow equations are:

$$s_i^k = \sum_{j=1}^n Q_{ij}^k, \quad k = 1, \dots, o; i = 1, \dots, m,$$

$$d_j^k = \sum_{i=1}^m Q_{ij}^k, \quad k = 1, \dots, o; i = 1, \dots, n,$$

$$Q_{ij}^k \geq 0, \quad k = 1, \dots, o; i = 1, \dots, m; j = 1, \dots, n.$$

In addition, we introduce the following expression, which captures time:

$$t_{ij}^k Q_{ij}^k + h_{ij}^k = T_{ij}^k, \quad k = 1, \dots, o; i = 1, \dots, m; j = 1, \dots, n, \quad (4)$$

In view of the conservation of flow equations, we can define new demand price functions $\hat{\rho}_j^k, \forall k, \forall j$ as follows:

$$\hat{\rho}_j^k(Q) \equiv \rho_j^k(d, T_{ave}), \quad k = 1, \dots, o; j = 1, \dots, n.$$

If the demand at a demand market for a product is equal to zero, we remove that demand market from the network for that product since the corresponding time average would not be defined.

Also, we can define new supply price functions $\hat{\pi}_i^k, \forall k, \forall i$ as:

$$\hat{\pi}_i^k(Q) \equiv \pi_i^k(s), \quad k = 1, \dots, o; i = 1, \dots, n,$$

which allow us to construct a variational inequality formulation governing the equilibrium conditions below with nice features for computations. We assume that all the functions in the model are continuous.

The Network Economic Equilibrium Conditions

The network economic equilibrium conditions for cybercrime have been achieved if for all products k ; $k = 1, \dots, o$, and for all pairs of markets (i, j) ; $i = 1, \dots, m$; $j = 1, \dots, n$, the following conditions hold:

$$\hat{\pi}_i^k(Q^*) + c_{ij}^k(Q^*) \begin{cases} = \hat{\rho}_j^k(Q^*), & \text{if } Q_{ij}^{k*} > 0 \\ \geq \rho_j^k(Q^*), & \text{if } Q_{ij}^{k*} = 0, \end{cases}$$

where recall that $\hat{\pi}_i^k$ denotes the price of product k at source location i , c_{ij}^k denotes the unit transaction cost associated with k between (i, j) , and $\hat{\rho}_j^k$ is the demand price of k at demand market j . Q_{ij}^{k*} is the equilibrium flow of product k between i and j with Q^* being the vector of all such flows.

We define the feasible set $K \equiv \{Q | Q \in R_+^{omn}\}$.

VI Formulation of the Equilibrium Conditions

Theorem: Variational Inequality Formulation

A product flow pattern $Q^ \in K$ is a cybercrime network economic equilibrium if and only if it satisfies the variational inequality problem:*

$$\sum_{k=1}^o \sum_{i=1}^m \sum_{j=1}^n \left[\hat{\pi}_i^k(Q^*) + c_{ij}^k(Q^*) - \hat{\rho}_j^k(Q^*) \right] \times (Q_{ij}^k - Q_{ij}^{k*}) \geq 0, \quad \forall Q \in K.$$

The above variational inequality problem can be put into standard form (see Nagurney (1999)): determine $X^* \in \mathcal{K}$, such that

$$\langle F(X^*), X - X^* \rangle \geq 0, \quad \forall X \in \mathcal{K}.$$

We define $\mathcal{K} \equiv K$, $X \equiv Q$, and $F(X) \equiv (F_{kij}(X)); k = 1, \dots, o; i = 1, \dots, m; j = 1, \dots, n$, where $F_{kij} = \hat{\pi}_i^k(Q) + c_{ij}^k(Q) - \hat{\rho}_j^k(Q)$.

The Algorithm

The Euler Method

At each iteration τ one solves the following problem:

$$X^{\tau+1} = P_{\mathcal{K}}(X^{\tau} - a_{\tau}F(X^{\tau})),$$

where $P_{\mathcal{K}}$ is the projection operator.

As shown in Dupuis and Nagurney (1993) and Nagurney and Zhang (1996), for convergence of the general iterative scheme, which induces the Euler method, among other methods, the sequence $\{a_{\tau}\}$ must satisfy: $\sum_{\tau=0}^{\infty} a_{\tau} = \infty$, $a_{\tau} > 0$, $a_{\tau} \rightarrow 0$, as $\tau \rightarrow \infty$.

Explicit Formulae

In particular, we have the following closed form expression for the product flows $k = 1, \dots, m$; $i = 1, \dots, m$; $j = 1, \dots, n$:

$$Q_{ij}^{k\tau+1} = \max\{0, Q_{ij}^{k\tau} + a_{\tau}(\hat{\rho}_j^k(Q^{\tau}) - c_{ij}^k(Q^{\tau}) - \hat{\pi}_i^k(Q^{\tau}))\}.$$

Numerical Examples: 2 Financial Products, 2 Supply Markets, and 2 Demand Markets

The network topology of the examples is as in Figure 3.

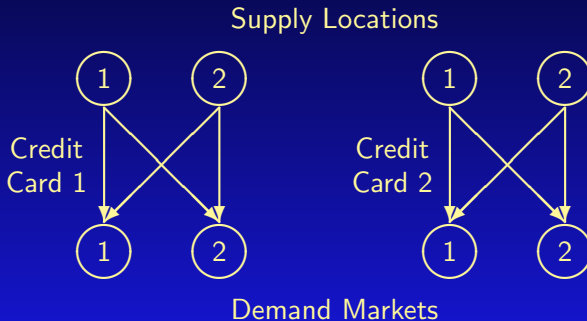

Figure 3: Topology of Examples

Numerical Examples: 2 Financial Products, 2 Supply Markets, and 2 Demand Markets

Example 1 The supply price functions are:

$$\pi_1^1(s) = 5s_1^1 + s_2^1 + 2, \quad \pi_2^1(s) = 2s_2^1 + s_1^1 + 1,$$

$$\pi_1^2(s) = 2s_1^2 + s_1^1 + 1, \quad \pi_2^2(s) = s_2^2 + .5s_2^1 + 1.$$

The unit transaction cost functions are:

$$c_1^1(Q) = .03Q_{11}^1{}^2 + 3Q_{11}^1 + 1, \quad c_{21}^1(Q) = .02Q_{21}^1{}^2 + 2Q_{21}^1 + 2,$$

$$c_{11}^2(Q) = .01Q_{11}^2{}^2 + Q_{11}^2 + 1, \quad c_{21}^2(Q) = .001Q_{21}^2{}^2 + .1Q_{21}^2 + 1,$$

$$c_{12}^1(Q) = .01Q_{12}^1{}^2 + Q_{12}^1 + 1, \quad c_{22}^1(Q) = .01Q_{22}^1{}^2 + Q_{22}^1 + 1,$$

$$c_{12}^2(Q) = .01Q_{12}^2{}^2 + Q_{12}^2 + 1, \quad c_{22}^2(Q) = .02Q_{22}^2{}^2 + 2Q_{22}^2 + 2,$$

and the demand price functions are:

$$\rho_1(1) = -2d_1^1 - d_1^2 - .5T_{ave,1}^1 + 500, \quad \rho_1^2(d) = -3d_1^2 - d_1^1 - .1T_{ave,1}^2 + 300,$$

$$\rho_2^1(d, T_{ave}) = -d_2^1 - .5d_2^2 - .2T_{ave,2}^1 + 200, \quad \rho_2^2(d, T_{ave}) = -2d_2^2 - d_2^1 - .1T_{ave}^2$$

Numerical Examples: 2 Financial Products, 2 Supply Markets, and 2 Demand Markets

Example 1 The time expressions are:

$$T_{11}^1 = .1Q_{11}^1 + 10, \quad T_{21}^1 = .5Q_{21}^1 + 5,$$

$$T_{11}^2 = .1Q_{11}^2 + 20, \quad T_{21}^2 = .5Q_{21}^2 + 15,$$

$$T_{12}^1 = .1Q_{12}^1 + 10, \quad T_{22}^1 = .1Q_{22}^1 + 10,$$

$$T_{12}^2 = .5Q_{12}^2 + 5, \quad T_{22}^2 = .5Q_{22}^2 + 10,$$

so that

$$T_{ave,1}^1 = \frac{T_{11}^1 Q_{11}^1 + T_{21}^1 Q_{21}^1}{d_1^1}, \quad T_{ave,1}^2 = \frac{T_{11}^2 Q_{11}^2 + T_{21}^2 Q_{21}^2}{d_1^2}.$$

$$T_{ave,2}^1 = \frac{T_{12}^1 Q_{12}^1 + T_{22}^1 Q_{22}^1}{d_2^1}, \quad T_{ave,2}^2 = \frac{T_{12}^2 Q_{12}^2 + T_{22}^2 Q_{22}^2}{d_2^2}.$$

The Euler method converged to the solution reported in Tables 1 and 2.

Example 2

Example 2

Example 2 has the same data as Example 1 except that now we have a modification in the demand price function associated with the second product at demand market 2 so that:

$$\rho_2^2(d, T_{ave}) = -2d_2^2 - d_2^1 - .1T_{ave,2}^2 + 200.$$

Such a change might represent that the value of this financial product has increased at that demand market.

Example 3

Example 3

Example 3 was constructed from Example 2 and had the same data except that we increased the fixed terms in all the transaction cost functions so that:

$$c_1^1(Q) = .03Q_{11}^1{}^2 + 3Q_{11}^1 + 10, \quad c_{21}^1(Q) = .02Q_{21}^1{}^2 + 2Q_{21}^1 + 20,$$

$$c_{11}^2(Q) = .01Q_{11}^2{}^2 + Q_{11}^2 + 10, \quad c_{21}^2(Q) = .001Q_{21}^2{}^2 + .1Q_{21}^2 + 10,$$

$$c_{12}^1(Q) = .01Q_{12}^1{}^2 + Q_{12}^1 + 10, \quad c_{22}^1(Q) = .01Q_{22}^1{}^2 + Q_{22}^1 + 10,$$

$$c_{12}^2(Q) = .01Q_{12}^2{}^2 + Q_{12}^2 + 10, \quad c_{22}^2(Q) = .02Q_{22}^2{}^2 + 2Q_{22}^2 + 20.$$

This could represent the situation that the cybercriminals have a harder time fencing all the products at all the demand markets. The results are reported in Tables 1 and 2.

Managerial Insights

- The above numerical examples, although stylized, provide important managerial insights that cybersecurity professionals may take advantage of in securing their data.

Managerial Insights

- The above numerical examples, although stylized, provide important managerial insights that cybersecurity professionals may take advantage of in securing their data.
- The examples show the quantified impacts of changes in the data on the equilibrium financial product flows, and on the incurred demand prices and average times for product delivery.

Managerial Insights

- The above numerical examples, although stylized, provide important managerial insights that cybersecurity professionals may take advantage of in securing their data.
- The examples show the quantified impacts of changes in the data on the equilibrium financial product flows, and on the incurred demand prices and average times for product delivery.
- The results are consistent with existing data on hacked credit cards. For example, Goncharov (2012) reports that the cost, that is, the supply price, of hacking into various accounts can range anywhere from \$16 to over \$325. Also, as reported in Ablon, Libicki, and Golay (2014), following an initial breach, the markets may get flooded with cybercrime products leading to a decrease in prices, which the structure of our demand price functions capture.

- Credit cards acquired in the Target breach initially fetched from \$20 to \$135 depending on the type of card, expiration date as well as limit (cf. Ablon, Libicki, and Golay (2014)). Although our numerical study did not focus on a specific historical data breach, the results are not inconsistent with results obtained in practice.

- Credit cards acquired in the Target breach initially fetched from \$20 to \$135 depending on the type of card, expiration date as well as limit (cf. Ablon, Libicki, and Golay (2014)). Although our numerical study did not focus on a specific historical data breach, the results are not inconsistent with results obtained in practice.
- Finally, the model captures the crucial time element in the demand market pricing of products obtained through cybercrime with a focus on financial services.

Multifirm Models of Cybersecurity Investment

Competition vs. Cooperation

Multifirm Models of Cybersecurity Investment

This part of the presentation is based on the paper, Multifirm Models of Cybersecurity Investment Competition vs. Cooperation and Network Vulnerability, Anna Nagurney and Shivani Shukla, where many references and additional theoretical and numerical results can be found.

Investing in Cybersecurity

There is a growing interest in developing rigorous frameworks for cybersecurity investments.

As reported in Glazer (2015), JPMorgan was expected to double its cybersecurity spending in 2015 to \$500 million from \$250 million in 2014.

According to Purnell (2015), the research firm Gartner reported in January 2015 that the global information security spending would increase by 7.6% in 2015 to \$790 billion and by 36% by 2018 to \$101 billion.

It is clear that making the best cybersecurity investments is a very timely problem and issue.

Common Features of the Models

We describe three different models of multifirm cybersecurity investments.

The first model is a Nash Equilibrium (NE) one capturing noncooperative behavior; the second and third are cooperative models, using Nash Bargaining (NB) and System-Optimization (S-O) concepts, respectively.

We assume that there are m firms in the “network.” These firms can be financial service firms, energy firms, manufacturing firms, or even retailers.

Each firm i ; $i = 1, \dots, m$, in the network is interested in determining how much it should invest in cybersecurity with the cybersecurity level or, simply, security level of firm i denoted, wlog, by s_i ; $i = 1 \dots, m$.

Common Features of the Models

The cybersecurity level s_i of each firm i must satisfy the following constraint:

$$0 \leq s_i \leq u_{s_i}, \quad i = 1, \dots, m,$$

where $u_{s_i} < 1$, and is also greater than zero, is the upper bound on the security level for firm i .

A value of a cybersecurity level of 1 would imply perfect security, which is not achievable. When $s_i = 0$ the firm has no security. We group the security levels of all firms into the m -dimensional vector s .

Common Features of the Models

In order to attain security level s_i , firm i encumbers an investment cost $h_i(s_i)$ with the function assumed to be continuously differentiable and convex.

For a given firm i , $h_i(0) = 0$ denotes an entirely insecure firm and $h_i(1) = \infty$ is the investment cost associated with complete security for the firm, as in Shetty et al. (2009) and Shetty (2010). An example of a suitable $h_i(s_i)$ function that we use in this paper is

$$h_i(s_i) = \alpha_i \left(\frac{1}{\sqrt{(1 - s_i)}} - 1 \right)$$

with $\alpha_i > 0$. Such a function was utilized in Nagurney and Nagurney (2015), in Nagurney, Nagurney, and Shukla (2015), and in Nagurney, Daniele, and Shukla (2015).

Common Features of the Models

The network security level, \bar{s} , is the average security, given by:

$$\bar{s} = \frac{1}{m} \sum_{j=1}^m s_j.$$

The vulnerability of firm i , $v_i = (1 - s_i)$, and the network vulnerability, $\bar{v} = (1 - \bar{s})$.

Common Features of the Models

Following Shetty (2010), the probability p_i of a successful attack on firm i ; $i = 1, \dots, m$ is

$$p_i = (1 - s_i)(1 - \bar{s}), \quad i = 1, \dots, m,$$

where $(1 - \bar{s})$ is the probability of an attack on the network and $(1 - s_i)$ is the probability of success of such an attack on firm i .

Common Features of the Models

Each firm i ; $i = 1, \dots, m$ has a utility associated with its wealth W_i , denoted by $f_i(W_i)$, which is increasing, and is continuous and concave. The form of the $f_i(W_i)$ that we use is $\sqrt{W_i}$ (see Shetty et al. (2009)). Such a function is increasing, continuous, and concave.

Also, a firm i is faced with damage D_i if there is a successful cyberattack on it.

Common Features of the Models

The expected utility $E(U_i)$ of firm i ; $i = 1, \dots, m$, is given by the expression:

$$E(U_i) = (1 - p_i)f_i(W_i) + p_i(f_i(W_i - D_i)) - h_i(s_i).$$

We may write $E(U_i) = E(U_i(s))$, $\forall i$. Each $E(U_i(s))$ is strictly concave with respect to s_i under the assumed functional forms above since we also know that each $h_i(s_i)$; $i = 1, \dots, m$ is strictly convex.

The Nash Equilibrium Model of Cybersecurity Investments

We seek to determine a security level pattern $s^* \in K^1$, where $K^1 = \prod_{i=1}^m K_i^1$ and $K_i^1 \equiv \{s_i | 0 \leq s_i \leq u_{s_i}\}$, such that the firms will be in a state of equilibrium with respect to their cybersecurity levels. K^1 is convex since it is a Cartesian product of the firms' feasible sets with each such set being convex since it corresponds to box-type constraints.

Definition: Nash Equilibrium in Cybersecurity Levels

A security level pattern $s^* \in K^1$ is said to constitute a cybersecurity level Nash equilibrium if for each firm i ; $i = 1, \dots, m$:

$$E(U_i(s_i^*, \hat{s}_i^*)) \geq E(U_i(s_i, \hat{s}_i^*)), \quad \forall s_i \in K_i^1,$$

where

$$\hat{s}_i^* \equiv (s_1^*, \dots, s_{i-1}^*, s_{i+1}^*, \dots, s_m^*).$$

VI Formulation of the NE Model

Theorem: Variational Inequality Formulation of Nash Equilibrium in Cybersecurity Levels

Since for each firm i ; $i = 1, \dots, m$ the expected profit function $E(U_i(s))$ is concave with respect to the variable s_i , and is continuously differentiable, and the feasible set K^1 is convex, we know that $s^ \in K^1$ is a Nash equilibrium in cybersecurity levels according to the Definition if and only if it satisfies the VI*

$$-\sum_{i=1}^m \frac{\partial E(U_i(s^*))}{\partial s_i} \times (s_i - s_i^*) \geq 0, \quad \forall s \in K^1;$$

or, if and only if it satisfies the VI

$$\sum_{i=1}^m \left[\frac{\partial h_i(s_i^*)}{\partial s_i} + [f_i(W_i) - f_i(W_i - D_i)] \left[\frac{1}{m} \sum_{j=1}^m s_j^* - 1 - \frac{1}{m} + \frac{s_i^*}{m} \right] \right] \times (s_i - s_i^*) \geq 0, \quad \forall s \in K^1.$$

Algorithm for the Solution of the NE Model

We can apply the Euler method, presented earlier to solve this model

In view of the simple structure of the underlying feasible set, the Euler method yields at each iteration closed form expressions for the security levels: i ; $i = 1, \dots, m$ given by:

$$s_i^{\tau+1} = \max\{0, \min\{u_{s_i}, s_i^{\tau} + a_{\tau}(-\frac{\partial h_i(s_i^{\tau})}{\partial s_i^{\tau}} - (f_i(W_i) - f_i(W_i - D_i))) \\ \left[\frac{1}{m} \sum_{j=1}^m s_j^{\tau} - 1 - \frac{1}{m} + \frac{s_i^{\tau}}{m} \right] \}\}.$$

The Nash Bargaining Model of Cybersecurity Investments

The bargaining model proposed by Nash (1950b, 1953) is based on axioms and focused on two players, that is, decision-makers. The framework easily generalizes to m decision-makers, as noted in Leshem and Zehavi (2008). An excellent overview can be found in Binmore, Rubinstein, and Wolinsky (1989) and in the book by Muthoo (1999).

Let $E(U_j^{NE})$ denote the expected utility of firm j evaluated at the Nash equilibrium security level solution. $E(U_j^{NE})$ is the disagreement point of firm j , according to the bargaining framework.

The Nash Bargaining Model of Cybersecurity Investments

The objective function underlying the Nash bargaining model of cybersecurity investments is:

$$Z^1 = \prod_{j=1}^m (E(U_j(s)) - E(U_j^{NE})).$$

The optimization problem to be solved is then:

$$\text{Maximize } \prod_{j=1}^m (E(U_j(s)) - E(U_j^{NE}))$$

subject to:

$$E(U_j(s)) \geq E(U_j^{NE}), \quad j = 1, \dots, m,$$
$$s \in K^1.$$

We define the feasible set K^2 consisting of the above constraints, which we know is convex.

The System-Optimization Model of Cybersecurity Investments

Under system-optimization, the objective function becomes:

$$Z^2 = \sum_{j=1}^m E(U_j(s))$$

and the feasible set remains as for the Nash equilibrium problem, that is, $s \in K^1$.

Hence, the system-optimization cybersecurity investment problem is to:

$$\text{Maximize } \sum_{j=1}^m E(U_j(s))$$

subject to:

$$s \in K^1.$$

A Numerical Case Study

Solutions of the Nash Equilibrium model were computed by applying the Euler method, with the Euler method implemented in Matlab on a Lenovo G410 laptop with an Intel Core i5 processor and 8GB RAM.

The convergence tolerance was set to 10^{-5} , so that the algorithm was deemed to have converged when the absolute value of the difference between each successively computed security level was less than or equal to 10^{-5} . The sequence $\{a_\tau\}$ was set to: $.1\{1, \frac{1}{2}, \frac{1}{2}, \frac{1}{3}, \frac{1}{3}, \frac{1}{3}, \dots\}$.

We initialized the Euler method by setting the security levels at their lower bounds. The upper bounds on the security levels $u_{s_i} = 0.99, \forall i$.

A Numerical Case Study

The solutions to the Nash Bargaining and System-Optimization models were computed by applying the Interior Point Method in the SAS NLP Solver. The algorithm was called upon while using SAS Studio, a web browser-based programming environment. The maximum optimality error, in each case example below, was 5×10^{-7} for the S-O solutions.

A Numerical Case Study

Wealth, damages, and investment costs are given in US dollars in millions. The α_i values in the cybersecurity investment functions across all examples are the number of employees in millions based on the most recently available public data.

We consider two retailers. Firm 1 represents the second largest discount retailer in the United States, Target Corporation. The firm, in January 2014, announced that the security of 70 million of its users was breached and their information compromised. Credit card information of 40 million users was used by hackers to generate an estimated \$53.7 million in the black market as per Newsweek (2014).

A Numerical Case Study

Firm 2 represents Home Depot, a popular retailer in the home improvement and construction domain. Products available under these categories are also sold through Target which makes them compete for a common consumer base. The company was struggling with high turnover and old software which led to a compromise of 56 million users (Newsweek (2014)).

Firm 1 suffered \$148 million in damages, according to the Consumer Bankers Association and the Credit Union National Association (Newsweek (2014)). Home Depot incurred a \$62 million in legal fees and staff overtime to deal with their cyber attack in 2014. Additionally, it paid \$90 million to banks for re-issuing debit and credit cards to users who were compromised (Newsweek (2014)).

A Numerical Case Study

We use the annual revenue data for the firms to estimate their wealth. Hence, in US\$ in millions, $W_1 = 72600$; $W_2 = 78800$. The potential damages these firms stand to sustain in the case of similar cyberattacks as above in the future amount to (in US\$ in millions): $D_1 = 148.0$; $D_2 = 152$.

As in Shetty et al. (2009), we assume that the wealth functions are of the following form:

$$f_1(W_1) = \sqrt{W_1}; \quad f_2(W_2) = \sqrt{W_2}.$$

The cybersecurity investment cost functions are:

$$h_1(s_1) = 0.25\left(\frac{1}{\sqrt{1-s_1}} - 1\right); \quad h_2(s_2) = 0.30\left(\frac{1}{\sqrt{1-s_2}} - 1\right).$$

The parameters $\alpha_1 = .25$ and $\alpha_2 = .30$ are the number of employees of the respective firms in millions, thereby, representing their size.

Results

Results for the Nash Equilibrium model, the Bargaining Nash model, and the System-Optimization model for cybersecurity investments are summarized in the Table.

Solution	NE	NB	S-O
s_1^*	0.384	0.443	0.460
s_2^*	0.317	0.409	0.388
v_1	0.616	0.557	0.540
v_2	0.683	0.591	0.612
\bar{s}^*	0.350	0.426	0.424
\bar{v}	0.650	0.574	0.576
$E(U_1)$	269.265	269.271	269.268
$E(U_2)$	280.530	280.531	280.534

Table 5: Results for NE, NB, and S-O for Target and Home Depot

Results

The Nash equilibrium security level for Firm 1 is 0.384 and that for Firm 2 is .317, indicating that neither firm may be well-prepared to ward off against cyber threats. The network security is .35 and the network vulnerability is .65. Firm 2 achieves a higher expected utility than Firm 1 under the Nash Equilibrium solution.

Target Corporation is part of the Retail Cyber Intelligence Sharing Center through which the firm shares cyber threat information with other retailers that are part of the Retail Industry Leaders Association and also with public stakeholders such as the U.S. Department of Homeland Security, and the F.B.I (RILA (2014)). Even Home Depot has expressed openness towards the sharing threat information.

Sensitivity Analysis

We report the results for sensitivity analysis by **increasing the values of the D_i parameters for $i = 1, 2$** . The wealth and alpha parameters are fixed as follows: (in US\$ in millions) $W_1 = 72600$, $W_2 = 78800$; (in millions) $\alpha_1 = 0.25$, $\alpha_2 = 0.30$. The solutions are reported in the following Tables.

Parameters		NE		NB		S-O	
D_1	D_2	$E(U_1)$	$E(U_2)$	$E(U_1)$	$E(U_2)$	$E(U_1)$	$E(U_2)$
24800	25200	268.476	279.648	268.485	279.658	268.484	279.659
34800	35200	268.377	279.542	268.386	279.551	268.385	279.552
44800	45200	268.290	279.451	268.300	279.461	268.300	279.461

Table 6: Expected Utilities for NE, NB, and S-O for Target and Home Depot for Varying D_i Parameters for $\alpha_1 = .25$ and $\alpha_2 = .30$

Sensitivity Analysis

Parameters		NE			NB			S-O		
D_1	D_2	s_1^*	s_2^*	\bar{v}	s_1^*	s_2^*	\bar{v}	s_1^*	s_2^*	\bar{v}
24800	25200	.924	.915	.08040	.933	.924	.07165	.933	.924	.07166
34800	35200	.935	.927	.06890	.943	.935	.06144	.943	.934	.06145
44800	45200	.943	.935	.06090	.949	.942	.05431	.949	.942	.05432

Table 7: Network Vulnerability \bar{v} for NE, NB, and S-O for Target and Home Depot for Varying D_i Parameters for $\alpha_1 = .25$ and $\alpha_2 = .30$

Sensitivity Analysis

The network vulnerability is consistently the lowest for the NB solution concept, demonstrating the benefit of bargaining for cooperation in cybersecurity. The increase in expected utilities on employing NB over NE is US\$ 10,193 for Target and US\$ 10,346 for Home Depot in the scenario wherein $D_1 = 44800$, $D_2 = 45200$. Comparison of S-O and NB shows an increase of US\$ 515 for Home Depot but a decrease of US\$ 513 for Target when $D_1 = 44800$, $D_2 = 45200$.

Additional Sensitivity Analysis

We now report the results for additional sensitivity analysis by increasing the values of the D_i parameters for $i = 1, 2$ where the wealth and alpha parameters are fixed as follows: (in US\$ in millions): $W_1 = 72600$, $W_2 = 78800$; (in millions), $\alpha_1 = 100.00$, $\alpha_2 = 120.00$. The results are reported in the subsequent Tables. The higher alpha parameters result in a significant increase in expected utilities as we move from NE to NB and S-O.

Parameters		NE		NB		S-O	
D_1	D_2	$E(U_1)$	$E(U_2)$	$E(U_1)$	$E(U_2)$	$E(U_1)$	$E(U_2)$
24800	25200	222.472	235.991	223.541	237.087	223.410	237.220
34800	35200	210.460	223.098	211.619	224.278	211.517	224.381
44800	45200	200.039	212.090	201.276	213.340	201.212	213.405

Table 8: Expected Utilities for NE, NB, and S-O for Target and Home Depot for Varying D_i Parameters for $\alpha_1 = 100.00$ and $\alpha_2 = 120.00$

Additional Sensitivity Analysis

Parameters		NE			NB			S-O		
D_1	D_2	s_1^*	s_2^*	\bar{v}	s_1^*	s_2^*	\bar{v}	s_1^*	s_2^*	\bar{v}
24800	25200	.169	.066	.88285	.262	.164	.78711	.265	.161	.78719
34800	35200	.289	.197	.75705	.369	.281	.67496	.371	.279	.67502
44800	45200	.374	.288	.66915	.444	.363	.59661	.445	.362	.59665

Table 9: Network Vulnerability \bar{v} for NE, NB, and S-O for Target and Home Depot for Varying D_i Parameters $\alpha_1 = 100.00$ and $\alpha_2 = 120.00$

Additional Sensitivity Analysis

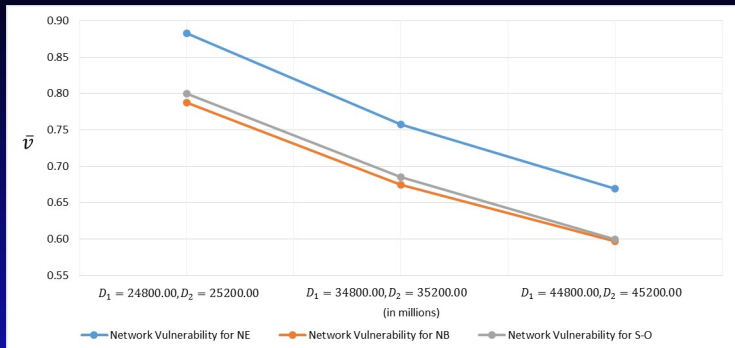

Figure 4: Representation of Table Showing Comparison of Network Vulnerability \bar{v} for NE, NB, and S-O with Varying D_i Parameters $\alpha_1 = 100.00$ and $\alpha_2 = 120.00$

The network vulnerability is consistently the lowest for the NB solution, signifying the benefits of cooperation for cybersecurity.

Cybersecurity and Supply Chains

Figure 5: Supply chains are also vulnerable to cyber attacks and can serve as entre points

Cybersecurity, Supply Chains, and Game Theory

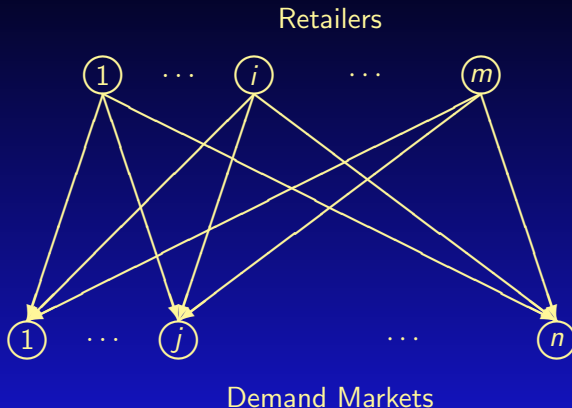

Figure 6: The Structure of the Supply Chain Network Game Theory Model

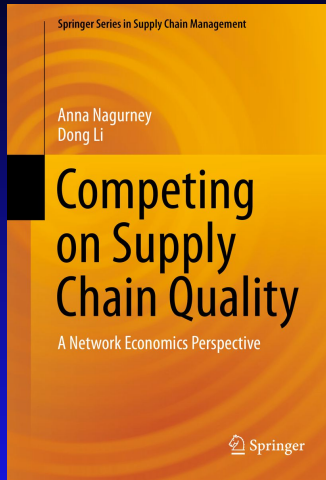

Some More of Our Recent Work

A Supply Chain Game Theory Framework for Cybersecurity Investments Under Network Vulnerability, A. Nagurney, L.S. Nagurney, and S. Shukla (2015), in: *Computation, Cryptography, and Network Security*, N.J.Daras and M.Th. Rassias, (Eds.), Springer, pp 381-398.

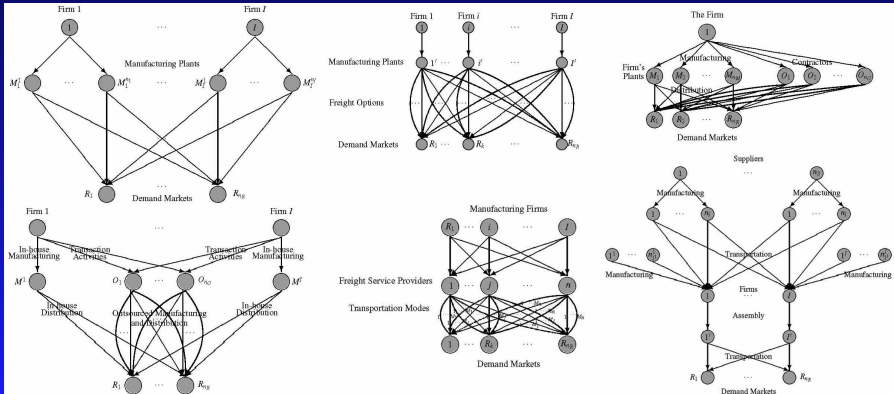

A Game Theory Model of Cybersecurity Investments with Information Asymmetry, A. Nagurney and L.S. Nagurney (2015), *Netnomics* 16(1-2), pp 127-148.

Cybersecurity Investments with Nonlinear Budget Constraints: Analysis of the Marginal Expected Utilities, P. Daniele, A. Maugeri, and A. Nagurney (2016), invited paper for *Operations Research, Engineering, and Cyber Security*, Th.M. Rassias and N.J. Daras, (Eds.), Springer International Publishing Switzerland.

Our Latest Supply Chain Book

In the book, we present supply chain network models and tools to investigate, amongst other topics, information asymmetry, impacts of outsourcing on quality, minimum quality standards, applications to industries such as pharma and high tech, freight services and quality, and the identification of which suppliers matter the most to both individual firms' supply chains and to that of the supply chain network economy.

Summary and Conclusions

- In the final part of this presentation, we overviewed our work on **network vulnerability** from a cybersecurity perspective. Our “clients” were retailers, who have also encountered a **growing number of cyberattacks**. Additional results we have obtained for case studies in financial services and in the energy sector

Summary and Conclusions

- In the final part of this presentation, we overviewed our work on **network vulnerability** from a cybersecurity perspective. Our “clients” were retailers, who have also encountered a **growing number of cyberattacks**. Additional results we have obtained for case studies in financial services and in the energy sector
- The cybersecurity investment models that we prevented included Nash Equilibrium, Nash Bargaining, as well as System-Optimization models. **The results demonstrate the relevance of cooperation with the most practical cooperative model being that of Nash Bargaining.**

Summary and Conclusions

- In the final part of this presentation, we overviewed our work on **network vulnerability** from a cybersecurity perspective. Our “clients” were retailers, who have also encountered a **growing number of cyberattacks**. Additional results we have obtained for case studies in financial services and in the energy sector
- The cybersecurity investment models that we prevented included Nash Equilibrium, Nash Bargaining, as well as System-Optimization models. **The results demonstrate the relevance of cooperation with the most practical cooperative model being that of Nash Bargaining.**
- Our research integrates inputs from practitioners with the goal of providing prescriptive analytics for decision-making for cybersecurity investments.

THANK YOU!

The Virtual Center for Supernetworks

Supernetworks for Optimal Decision-Making and Improving the Global Quality of Life

Center Associates of the Virtual Center for Supernetworks

The Virtual Center for Supernetworks is an interdisciplinary center at the Isenberg School of Management that advances knowledge on large-scale networks and integrates operations research and management science, engineering, and economics. Its Director is Dr. Anna Nagurney, the John F. Smith Memorial Professor of Operations Management.

Mission: The Virtual Center for Supernetworks fosters the study and application of supernetworks and serves as a resource on networks ranging from transportation and logistics, including supply chains, and the Internet, to a spectrum of economic networks.

The Applications of Supernetworks Include: decision-making, optimization, and game theory; supply chain management; critical infrastructure from transportation to electric power networks; financial networks; knowledge and social networks; energy, the environment, and sustainability; cybersecurity; Future Internet Architectures; risk management; network vulnerability, resiliency, and performance metrics; humanitarian logistics and healthcare.
